# JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JULY-DECEMBER 1934

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals except those starred will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Two journals may be borrowed at a time. No journals are available prior to 1925. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents at one and 12 cents if two periodicals are requested). Thus most of these journals are accessible to the general practitioner.

# SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation, "E," Editorial, "C," Correspondence, "ME," Medical Economics, "ab," abstract, the star (\*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2108

Academy Japan 202  
Albert Medal of Royal Society of Arts 500  
Alvaresa 417  
American Association for Study of Goltter 1863  
American Legion award 416—E 496  
Bell (Mary Ellis) 51  
Cameron 1077  
Capps (Joseph A.) 116  
Clark (John C.) 51

## PRIZES—Continued

- Cleveland Academy of Medicine poetry 926, 1962  
Fiske awarded 52  
health contest (Lutchenbacher) 684  
Horsley (John) Memorial, 52  
International Foundation of Gynecology and Obstetrics 1002  
Laciaro Medal 761  
Lombroso 57  
New Jersey Health and Sanitary Association 1629  
New York Academy of Medicine 1075  
Nobel (in medicine), 1352—F 1387 (in chemistry) 1785  
Priestly (Rayne Simpson), 51  
Rosenberger Medal, 1478  
Rumanian Medical Academy 1635  
Saunders Memorial Medal 1243  
Sedgwick Memorial Medal 1240  
Slacy (James P.) 360  
State Medical Society of Wisconsin gold seal 927  
Umberlo 1 orthopedic 420  
University of Bern for encephalitis research 1001  
University of Buffalo medal in ophthalmology 1459  
Ward Burdick Medal 196  
Wellcome Medal and Prize 197  
Williams (David) 57  
Woman's Medical College of Pennsylvania gold medals 196
- PROCINE** borate Tablets Procaine Borate and Epinephrine, 1708  
Epinephrine Solution (Abbott) 1067  
Hydrochloride See also under Anesthesia  
Plebitis  
hydrochloride blocking to influence trophic processes [Vishnevsky] 149—ab  
Hydrochloride Hypodermic Tablets (Abbott) 1067  
injections palpitation and nervousness after 860  
Neo Symphehrin Hydrochloride Hypodermic Tablets 917
- PROCTITIS** See Rectum  
**PROCTOCYCLYSIS** See Rectum  
**PROCTOLOGY** American Board on A M A resolution on 44  
**PRODIGIOSUS** toxins (Coley) Council report on 1067 1070—E  
**PROFESSORS** honored Soviet Union 1502  
**PROGNOSIS** See under specific diseases as  
Arteriosclerosis Heart disease  
**PROGLYN** in amenorrhea and menstrual irregularities 1011
- PROSTATE** See also Urethra prostatic  
abscess gonorrheal in 4 year old [Fox] \*748  
aerocystography, [Ross] 875—ab  
cancer, [Ewell] 288—ab [James] 1657—ab  
cancer adenocarcinoma metastasis to vertebral column [Dickson] 74—ab  
hypertrophy new shrinkage method for [Kilwin] 1987—ab  
infection diagnosis 1170  
inflammation See Prostatitis  
resection (transurethral electro) intravesical explosions complicating [Kretschmer] \*1144  
surgery transurethral [Caulk] 216—ab  
tumor sarcoma [Lowsley & Kimball] \*983
- PROSTATECTOMY** See also Prostate resection  
suprapubic defense of [Reyes] 1080—C (re ply) [Young] 1086—C (correction) 1243  
suprapubic trigonal loop traction in, [Lumb] 1892—ab  
suprapubic with immediate bladder closure drainage after [Haynes] \*174
- PROSTATITIS** chronic [Stutsman] 288—ab  
chronic diagnosis and treatment 1090  
postgonorrheal, 1970
- PROSTIGMINE** therapeutic action [Carmichael] 143—ab
- PROSTITUTION** Germany 1634  
legislation Irish Free State 848  
licensed abolished Japan 202
- PROTEIN** action (specific dynamic) [Hogler] 790—ab  
diet in hypertension 937  
diet requirements 620  
digestion vs. that of carbohydrates [Rehfuß] \*1600  
economy in oxygen deficiency [Elias] 1340—ab  
in Blood See Blood  
in Urine See Albuminuria Urine  
nature of antibodies 1380—E  
relation to osmotic pressure of serum and of lymph 1952—E  
Therapy See Gonorrhea  
tissue composition 706—E
- PROTEO BREAD** 992
- PRUNES** California Educational Advertising 1453  
strained brands accepted 111  
Suesweet Juice 993
- PRURITUS** and salicylic acid in alcohol for [Crech] 873—ab  
and x rays for 128  
balnea 509

## PRURITUS—Continued

- lesteric 2047  
rubac alcohol injection for [Wilson] 1025—ab
- PSIUBANTHROSI** congenital of leg bone graft for [Colonna] \*2012
- PSYCHOANALYSIS** originating in cervical spine [Nachlas] \*747
- PSITTACOSIS** 282  
in Germany 274 [Gulzelt] 1404—ab  
vaccination [Hitters] 870—ab
- PSORIASIS** in tropical countries [Lardo Castella] 206—C  
treatment low fat diet 56 [Grütz] 703—ab  
treatment rocinogen [Hoshi] 916—ab
- PSYCHIATRISTS** to Board of Education examination for New York City 1620  
problem of expert witnesses France 1007  
therapeutic abortion indications from standpoint of [Cheney] \*1014
- PSYCHIATRY** American Board of organized 1047 1717  
clinical and eugenics 1164  
Connecticut Society of formed 19.  
Deutscher Verein für Psychiatrie 1161  
attitudes at U of Colorado under Rockefeller Foundation 817
- PSYCHONALYSIS** convict Mrs. Mayer 361  
literature on case work in 136  
Society (first) Humanita 42.
- PSYCHOPATHOSIS** relation to migraine and epilepsy [Paskind] 78—ab  
treatment in general practice [Smith] \*1111
- PSYCHOSIS** See also Dementia Praecox in  
sanity Mental Disease  
in pernicious anemia 1529—ab  
of cyanide gas poisoning 854  
respiration in [Paterson] 377—ab
- PTERYGIUM** in papyrus Fibra 858
- PTOSIS** See Eyelids  
LUBERTY See Adolescence  
**PUBLIC HEALTH** See Health
- PUPERFAL INFECTION** [Mortland] 1807—ab  
prevention treatment practical measures [Watson] \*1745
- PULPITRUM** cervical erosions etc in [Barrott] \*1516  
gynecology in 2030—E  
hemorrhages treatment [Stedentopf] 224—ab  
held composition of leukocytes in [Boyd] 1959—ab
- PULSE** throttling effect on blood pressure [Wolf] 723—ab
- PUNCTURE** See Arteries Cisterna Magna  
Pleura Spinal Puncture
- PUPILS** arca vs retinal sensibility [Lucklesh] 631—ab  
Dilating See Mydriatics  
sign in ruptured ectopic pregnancy [Salmon] 1098—ab
- PURIFICATION** See Cathartics
- PURKINE JOHANNES** invention of histologic technique, 1583—ab
- PURPURA** diagnosis and treatment 773  
haemorrhagic, diagnosis treatment [Pemberton] 371—ab  
haemorrhagic thrombopenic with stomach cancer [Lawrence] 291—ab  
simplex 1560
- PUS** See also Infections pyogenic  
in Urine See Pyuria  
reaction in lungs disease [De Blas] 301—ab
- PYELITIS** granulular cause of renal pelvis hemorrhage [Ottow] 1661—ab  
of pregnancy and ureteral catheterization [von Mikulicz Radecki] 456—ab  
or appendicitis with otitis media 1252  
therapeutic abortion in [von Mikulicz Radecki] 1662—ab
- PYELOGRAPHY** injection of perirenal lymphatics [Abeshouse] 1406—ab
- PYELO URETEROGRAPHY** improved, [Howard] 72—ab
- PYLORUS** obstruction gastric lavage in [Freeman] 448—ab  
spasms treatment 1246  
stenosis in infants Ramstedt's operation [von Haberer] 381—ab
- PYODERMIA** See also Carbuncle Furunculosis  
Isolated chancre like facial [Hoffmann] 1742—ab
- PYRETHRUM** sensitization complicating hay fever [Kampmeier] 205—C
- PYRIDIUM** See also Gonorrhea vaginitis  
hydrochloride pharmacology [Walton] 445—ab
- PYURIA** chronic ketogenic diet in [Rector] 873—ab  
treatment acidosis [Plum] 80—ab

## Q

- QUACKERY** regulation Japan 1553
- QUAKER BRAND** (gelatin) 993 (chocolate) 1539
- QUALITY** Dairy Vitamin D Milk 1069
- QUARANTINE** See also Scarlet Fever  
Farms See Tuberculosis bovine  
rules modified New York 686
- QUARRIES** See Granite
- QUARTZ** Cold Quartz Lamp See Ultraviolet Rays  
response of peritoneal tissue to [Miller & others] \*909 \*911
- QUINCK'S DILAS** See Fdema angio neuritic
- QUINCY** Brand Chocolate 260
- QUINIDINE** See Ventricular Fibrillation
- QUININ** See also Labor Induction  
antimalarial use [Buddee] 520—ab  
dermatitis effects on pneumococcus [MacLachlan] 1080—ab  
eruption from contraceptive [Ford] \*183  
idiosyncrasy and agranulocytic angina [Fitz Hugh] 1000—ab  
intravenous use 2070  
Treatment See Sclerosis multiple  
Urea Injection See Hydrocele
- QUINTILLIS** antiquity [Walsh] 1010—C  
Dionne [Dafco] \*673 684—F 1398

## R

- R O T C** See under Army U S
- RABBIT** fever See Tularemia
- RABIES** among foxes 614  
death from (California) 103 (New York City) 762  
incubation period in dogs 208 436 1726  
transmission by dog vaccinated 282  
vaccine (Cumming) 017  
vaccine efficacy 937  
vaccine (human) (Chloroform killed)—National 1309  
vaccine (Phenol killed)—Muldorf 1708
- RACIS** See also Negroes etc  
Aryan and Nordic myths 764
- RADIANT** energy source [Laurens] \*1447  
Heat See Heat, Infra Red Rays
- RADIATION** Mitogenic See Cells  
Therapy See Cancer, treatment Esophagus cancer
- RADICULOMYELITIS** See also  
Meningo radiculitis  
[Christiansen] 880—ab
- RADIO** A M A expresses appreciation to A B C 1230  
control of medical broadcasts Canada 1958  
in education National Advisory Council 1310  
—E (Parran resigns) 1715  
medical consultations on the high seas 2042  
noise protection against 766  
treatment of disease 1718
- RADIOLOGISTS** A M A resolution on exploitation by hospitals 45
- RADIOLOGY** Departments of See Hospitals  
Institute in Madras 420  
International Congress of (55th) (A M A Inlies) 45 1243  
Radiological Society of North America 928
- RADIOSENSITIVITY** problem [Cutler] \*1204
- RADIOTHERAPY** See Furunculosis
- RADIOTHERMY** See Short Waves
- RADIUM** center in Colombia 688  
Cone No 3 1084—B1  
Emanation See Radon  
gamma ray effect on wound healing [Nathan son] 528—ab  
gamma ray therapy dosage system [Pater son] 1810—ab  
History Madame Curie's achievements 1633  
implantation in cervix ureteral occlusion after [Bugbee] 1987—ab  
Imports U S 1161

## THE RÔLE OF THE GASTRO-INTESTINAL TRACT IN CONDITIONING DEFICIENCY DISEASE

THE SIGNIFICANCE OF DIGESTION AND ABSORPTION  
IN PERNICIOUS ANEMIA PELLAGRA AND  
"ALCOHOLIC" AND OTHER  
FORMS OF POLY-  
NEURITIS

MAURICE B. STRAUSS, M.D.  
BOSTON

Fifty-four years ago, Fenwick<sup>1</sup> wrote "The volume of the blood depends on the quantity of nutriment dissolved and absorbed by the digestive tract." Today one may expand his almost forgotten statement and say that the state of the blood and the integrity of the tissues of the body depend on the quantity and quality of nutriment dissolved and absorbed by the digestive tract. It is only within the past two decades that the qualitative as well as the quantitative aspects of nutrition have become generally known. Certainly it is only within the past few years that the importance of the role of the digestive tract has become apparent.

At the end of the nineteenth century the brilliant bacteriologic researches of Pasteur, Koch and those that followed them so overshadowed other developments in medicine that physicians became imbued with the thesis that only positive agents—the bacterium, the parasite, the toxin—could cause disease. In 1897, although Eijkman<sup>2</sup> clearly established the fact that a lack, a minus sign, a deficiency was responsible for beriberi, he was unwilling to accept such a heretical doctrine and suggested instead that foods such as polished rice, being overrich in starch produced a substance in the intestine which was poisonous to nerve cells and for which the outer layers of rice acted as an antidote. Each of the conditions considered in this paper has been thought in the past to be due to the action of similarly hypothetic toxins.

Eijkman, Hopkins, Mendel, McCollum and the host of others who have contributed to the modern knowledge of nutrition did so by means of studies on animals in which dietary deficiency disease was produced by the elimination of specific substances from the diet. A new concept, reviewed in this paper, is that deficiency disease in man may and frequently does develop because of some disturbance of the gastro-intestinal

tract in spite of an apparently adequate diet. Although Fenwick first suggested this possibility a half century ago, and numerous confirmatory observations have been recorded, the more immediate development of this concept is due to the fundamental work of Castle.<sup>3</sup>

In 1928, Castle demonstrated clearly for the first time that an asymptomatic abnormality of gastric secretion might condition a state of dietary deficiency irrespective of the adequacy of the diet. Since then, knowledge of the relationship of disorders of the gastro-intestinal tract to various dietary deficiency diseases has advanced rapidly. Pernicious anemia, pellagra, "alcoholic" and pregnancy polyneuritis, idiopathic hypochromic anemia, and the "toxemias" associated with intestinal obstruction and vomiting in pregnancy, among other conditions, may be due in many instances wholly or in part to deficiencies resulting from disturbances of the gastro-intestinal tract.

### PERNICIOUS ANEMIA

It has been known for many years that classic Addisonian pernicious anemia occurs in association with gastric anacidity. However, it remained for Castle's simple but ingenious observations to prove the etiologic role of a gastric defect.<sup>3</sup> He administered beefsteak daily to patients with pernicious anemia. No improvement occurred either clinically or in the state of the blood. Subsequently, beefsteak was eaten by a normal individual, recovered from his stomach after an hour, and administered to the same pernicious anemia patients with prompt improvement in the clinical aspect and the blood. This indicated that some process occurred in the normal human stomach which did not take place in the stomach in pernicious anemia.

It was next found that the reaction which occurred in the normal stomach could be produced equally well in vitro or in the stomach of the patient.<sup>4</sup> Beefsteak incubated with normal human gastric juice and then administered by tube or eaten by the patient and followed shortly by the administration of normal gastric juice was equally effective. However, gastric juice administered alone or twelve hours after the ingestion of beefsteak produced no response.<sup>4</sup> These observations indicated that gastric juice and beefsteak separately were inert and that there was a need for contact between them for this reaction.

Further experiments<sup>5</sup> showed that gastric juice freed from hydrochloric acid, pepsin and rennin

2 Eijkman Christiaan. Eine Beriberi ähnliche Krankheit der Hühner. *Virchows Arch f path Anat* 148: 523 1897.

remained equally effective in producing a satisfactory hematologic response in pernicious anemia after incubation with beefsteak. In addition, gastric juice obtained from a number of patients with achylia gastrica, who did not have pernicious anemia, was shown to react like normal gastric juice.<sup>6</sup> On the other hand, an artificial gastric juice prepared by the mixture of hydrochloric acid, pepsin and rennin and, in two instances, gastric juice containing normal amounts of acid and ferments recovered from two patients with atypical pernicious anemia were incapable of producing the reaction. It was shown that neither saliva nor pure duodenal secretion contains the "intrinsic factor" present in normal human gastric juice.

These observations indicated that pernicious anemia was a hitherto undescribed type of deficiency disease, one in which the deficiency was caused not by a defective diet but usually by the absence from the gastric juice of a specific heat-labile factor, that is not hydrochloric acid, pepsin, rennin or lipase.

Experiments carried out during the last few years<sup>7</sup> have shown that the "extrinsic factor" present in beefsteak is also present in the washed and precipitated proteins of beefsteak, in eggs, in autolyzed yeast, in wheat germ, in rice polishings, in an alcoholic extract of autolyzed yeast, and in hydrolyzed extracts of liver and that it is not destroyed by autoclaving at 120 C for five hours, a temperature which destroys vitamin B<sub>1</sub>. The substance is not associated with fats and carbohydrates and is not found in the two fairly complete proteins, casein and gluten, or in purified nucleoprotein and nucleic acid. In general, the distribution of the "extrinsic factor" that is capable of reacting with gastric juice to produce improvement of the blood in pernicious anemia closely approximates the distribution of vitamin B<sub>2</sub> (G), the antipellagra vitamin. However, there is considerable evidence at hand that these two substances, although associated, are not identical.<sup>8</sup>

If these observations are correct, an anemia identical with addisonian pernicious anemia and which corresponds to the classic type of deficiency disease should be produced by the deficiency of the dietary factor.<sup>9</sup> Indeed, the macrocytic anemia of the tropics described by Wills in India<sup>9</sup> is such a disease, and certain cases of pernicious anemia of pregnancy<sup>10</sup> and of sprue<sup>11</sup> fall into this class.

Furthermore, in consideration of Fenwick's apothem, other cases of anemia identical with addisonian pernicious anemia should be found in the presence of an adequate diet and a normal gastric secretion, because of inadequate absorption from the intestinal tract. The

first recorded case<sup>12</sup> of apparent pernicious anemia secondary to an intestinal disturbance occurred in a boy, aged 16 years, admitted to the service of Dr. Thomas Addison at Guy's Hospital in 1856. The colon at autopsy showed ulcerative and cicatricial lesions. Recently, Kcefer and his associates<sup>13</sup> have shown that a blood picture similar to pernicious anemia may develop in association with the prolonged diarrhea of chronic bacillary dysentery. Vaughan and Hunter<sup>14</sup> have shown that the same blood picture may occur in connection with the malabsorption of celiac disease (idiopathic steatorrhea). No doubt this factor also operates in certain cases of sprue.

Furthermore, a number of cases identical with pernicious anemia have been reported in individuals suffering from various organic abnormalities of the intestinal tract, such as multiple intestinal anastomoses and partial intestinal stenosis. Faber<sup>15</sup> in 1895 made the first report of such a case. The autopsy disclosed two fibrous strictures of the small intestine. The strictures were probably secondary to a healed tuberculous process.

Meulengracht<sup>16</sup> reviewed the literature on this subject to 1929 and added cases of his own to make a total of twenty-two, eighteen due to strictures of the small intestine, three to strictures of the colon and one to stricture of the cecum. Seyderhelm and his associates<sup>17</sup> in a report on "pernicious anemia" in dogs, produced experimentally by operative stricture of the small intestine, mention a patient with pernicious anemia secondary to such a stricture who recovered when the intestinal abnormality was surgically eradicated. Little, Zerfas and Trusler<sup>18</sup> recently described a case of pernicious anemia of similar causation, in which, however, the anemia was not relieved when the bowel was restored to its normal state, but continued to require liver therapy. Schlesinger<sup>19</sup> found the intrinsic factor described by Castle in the stomach of a patient with pernicious anemia secondary to intestinal stenosis, so that in this instance there is clear evidence in favor of faulty absorption.

The youngest patient with pernicious anemia that we have seen in our clinic was a boy, aged 8 years, in whom, as a result of two operations for intestinal obstruction following appendectomy, short circuits developed between various loops of the small intestine. Another of our patients was a man whose diet for years has been adequate and whose gastric juice contained the intrinsic factor, but because there are multiple intestinal anastomoses, he presumably cannot absorb the necessary material for blood formation. At least four of the patients with pernicious anemia secondary to intestinal lesions have been relieved of their anemia without operative intervention since the introduction of liver therapy.

It thus appears that pernicious anemia may result from any one of three mechanisms or from any combination of them: (1) the lack of a digestive juice in the stomach, (2) the absence of a substance associated with vitamin B<sub>12</sub> (G) from the diet or (3) the failure of absorption from the intestinal tract of the product of interaction of the stomach and dietary factors.

#### PELLAGRA

Pellagra as commonly seen in the endemic form, is probably due essentially to the lack of vitamin B<sub>12</sub> (G) in the diet. In the North however, with rare exceptions, pellagra is seen in individuals who have organic lesions or abnormalities of the gastro-intestinal tract or who are habitual alcoholic addicts. Spies and DeWolf<sup>20</sup> have shown that 'alcoholic' pellagra is identical with the endemic pellagra of the South. The effects of overindulgence in alcohol on the gastro-intestinal tract are so well known that they need not be discussed here. It is possible therefore that alcoholic pellagra may result from the combination of these gastro-intestinal disturbances, particularly the anorexia, vomiting and diarrhea, and the moderately faulty diet of many alcoholic subjects. Zimmerman, Cohen and Gildea<sup>21</sup> suggest that disturbances of digestion or disordered absorption may exist in these individuals so that vitamin B<sub>12</sub> will be wholly ineffective when administered by mouth but effective by parenteral injection. This, however, is as yet unproved.

Fifteen cases of pellagra secondary to cancer of the stomach, usually with an associated pyloric obstruction, have been reported by seven different authors,<sup>22</sup> and three cases secondary to pyloric obstruction from peptic ulcer have also been noted.<sup>23</sup> Cancer of the terminal ileum has been followed by pellagra in three instances.<sup>24</sup> Rectal stricture has been associated with the subsequent development of pellagra sixteen times.<sup>25</sup> Among miscellaneous diseases of the gastro-intestinal tract which have resulted in pellagra may be mentioned ulcerative colitis, five times,<sup>26</sup> gastro-enterostomy, five times,<sup>27</sup> jejunostomy, twice,<sup>28</sup> gastric syphilis, twice,<sup>29</sup> and esophageal stricture,<sup>22c</sup> duodenal feeding,<sup>30</sup> jejunal stenosis,<sup>22d</sup> ileac stenosis,<sup>22d</sup> dilatation of the colon<sup>30</sup> cloaca,<sup>22d</sup> amebic dysentery,<sup>22d</sup> and rectovaginal fis-

ture,<sup>22d</sup> once each. In addition, Boggs and Padgett<sup>22f</sup> have noted four cases of pellagra secondary to diarrhea associated with rectal disease and four cases secondary to cancer of the gastro-intestinal tract (location not specified).

In this clime pellagra has been observed secondary to ulcerative colitis, mucous colitis, carcinoma of the stomach, duodenal ulcer, diaphragmatic hernia, and stenosis of the small intestine. In most of these cases the gastro-intestinal lesion has prevented the patient from partaking of an adequate diet. However, in at least ten instances the diet was entirely adequate for the prevention of pellagra in an individual with a normal gastro-intestinal tract. A case mentioned by Boggs and Padgett<sup>22f</sup> is of particular interest because the patient, who had a cancer of the stomach, was on a liver diet for the prevention of anemia, yet pellagra developed. The fact that pellagra is usually seen in the North in association with chronic alcoholism or gastro-intestinal lesions suggests that the gastro-intestinal tract plays an important role in conditioning this deficiency disease.

#### MULTIPLE NEURITIS (BERIBERI)

Peripheral polyneuritis is endemic in the Orient and Labrador, where it is not an uncommon disease. In these regions the etiologic factor appears to be chiefly a faulty intake of vitamin B<sub>1</sub>. As is the case with pellagra, polyneuritis is rarely seen in the northern portion of the United States except when it is conditioned by gastro-intestinal factors. The most common of these factors is chronic alcoholism. Since John Coakley Lettison<sup>31</sup> in 1787 first described 'alcoholic' polyneuritis, a direct neurotoxic effect of alcohol has been considered to be the causative agent. Six years ago, however, Shattuck<sup>32</sup> suggested the possibility that a deficiency was the cause of this disease. Subsequently Minot, Cobb and I<sup>33</sup> investigated the gastro-intestinal function and dietary histories of fifty-seven patients with alcoholic polyneuritis. We found that over 80 per cent of our patients had gastric anacidity or hypacidity and that 95 per cent had partaken of grossly inadequate diets. Nausea, anorexia and vomiting were common complaints and led to further dietary deficiency. Recently, in order to rule out still further any possible direct neurotoxic effect of alcohol, six patients with alcoholic neuritis have been given between a pint and a quart of whisky daily, or the approximate amount they had taken daily for a long time before the observations were made. Relief of the neuritis under this regimen has occurred during the oral and hypodermic administration of large quantities of vitamin B.

The 'toxic' polyneuritis of pregnancy has been considered the result of a direct poisoning from a neurotoxin elaborated by the fetus or placenta. A recent report<sup>34</sup> gives a mortality rate of 76 per cent in this disease. Last year McDonald and I<sup>35</sup> pointed out the clinical and pathologic identity of this condition and beriberi and recorded the successful treatment of three cases of polyneuritis of pregnancy by the administration of adequate amounts of vitamin B. The disease occurs only after 'pernicious vomiting' of pregnancy.

It is thus apparent that the failure of the gastro-intestinal tract to retain food can cause this deficiency disease.

The French literature contains reports by four different authors of six cases of polyneuritis associated with pyloric stenosis secondary to peptic ulcer.<sup>36</sup> In all these cases there had been incessant vomiting caused by the obstruction, so that they were analogous to cases of polyneuritis in pregnancy following vomiting. Two of the patients were relieved by gastro-enterostomy. At the present time a discussion of the theory that a neurotoxic substance was formed in the retained contents of the dilated stomach is hardly necessary.

Five cases of beriberi secondary to celiac disease have been reported by Haas,<sup>37</sup> Keefer and Yang,<sup>38</sup> noted two cases resulting from chronic bacillary dysentery, and Eusterman and O'Leary,<sup>32c</sup> and Jones.<sup>39</sup> have observed it in ulcerative colitis. Kohn,<sup>40</sup> and Viets and Allen<sup>41</sup> report polyneuritis secondary to gastro-enterostomy, and Urmey and his associates<sup>42</sup> have reported a case in a patient with an entero-enterostomy which short-circuited all but 24 inches (61 cm) of small bowel. A case of polyneuritis secondary to a stricture of the sigmoid is also on record.<sup>43</sup> McVicar<sup>44</sup> observed two cases of polyneuritis in patients with jaundice. Study of the case histories reveals the fact that one patient lost more than 200 pounds (90.7 Kg.), and the second patient had excessive vomiting and diarrhea. Three cases of polyneuritis occurring in patients with persistent vomiting following operations on the biliary tract are recorded.<sup>45</sup> In the last five years at the Boston City Hospital, beriberi has been observed secondary to duodenal ulcer three times and once each secondary to gastric carcinoma, gastric polyps, and the Plummer-Vinson syndrome.

It thus appears that gastro-intestinal disturbances practically always condition the development of beriberi in those regions where it is not endemic.

#### OTHER CONDITIONS

Thus far the role of the gastro-intestinal tract in conditioning deficiencies of various parts of the vitamin B complex have been considered. Although scurvy and rickets, even in the temperate zone, are usually due to a direct dietary lack, certain cases of the former have been observed in adults suffering from peptic ulcer, and osteomalacia and tetany have been reported secondary to the disturbed intestinal absorp-

tion accompanying celiac disease<sup>46</sup> and sprue.<sup>47</sup> The more severe grades of iron deficiency manifested in hypochromic anemia are so commonly associated with faulty gastric secretion that the name "achlorhydric anemia" has been proposed. Both intestinal obstruction and the "pernicious" vomiting of pregnancy are associated with a "toxic" state considered in the past to be due to the absorption of a toxin formed in the obstructed intestine or by the production of conception. Within the past decade it has been demonstrated that the toxic symptoms following obstruction of the bowel are due to a loss of water and electrolytes from vomiting. If these materials are introduced into the bowel below the obstruction or administered parenterally, toxic symptoms do not appear. Recently the clinical, chemical and pathologic picture of pernicious vomiting in pregnancy has been reproduced experimentally in animals made to vomit by the administration of apomorphine.<sup>48</sup> The results of these experiments suggest that the toxic symptoms are due solely to the loss of water and electrolytes and hence are a manifestation of a deficiency rather than of a toxemia.

#### SUMMARY

Dietary deficiency diseases, particularly pernicious anemia and related macrocytic anemias, idiopathic hypochromic anemia, pellagra and "alcoholic" pregnancy and other forms of polyneuritis, among other conditions, in the temperate zone, are more frequently caused by conditioning gastro-intestinal disturbances than by inadequate diets.

### EVALUATION OF THE CAPILLARY RESISTANCE TEST IN THE DIAGNOSIS OF SUBCLINICAL SCURVY

DAVID GREENE, M.D.

NEW YORK

In the field of nutrition there have been evolved methods for the determination of deficiencies of the various vitamins in the diet. These methods, now definitely established, apply to both manifest and latent avitaminosis. The search is still continuing for finer methods which will detect the earliest manifestations—even before clinical signs become evident. In this connection there have recently appeared a number of papers concerning the antiscorbutic vitamin C.

Hess<sup>1</sup> in 1914 demonstrated, by means of the blood pressure tourniquet, the increased fragility of the blood capillaries in manifest scurvy as evidenced by the development of petechial spots along the forearm. He found that the test was positive in the majority of cases of this disease, indicating a weakness of the capillary vessel walls due to a failure on the part of the endothelial cells to form cement substance. In 1928 Ohnell,<sup>2</sup> too, established the value of the capillary resistance test in detecting cases of latent scurvy in a group of twenty-two cases in which vitamin C was entirely lacking or

was taken in very small quantities. In 1931 Gothlin,<sup>3</sup> with the aid of this test, inquired into the possibility of revealing much milder deficiencies in vitamin C, namely, "such as lie between the smallest discernible deviation from a normal vitamin C level and the highest deviation possible without giving rise to actual symptoms of the disease." The latter class together with the latent and manifest scurvy form a complex which might be termed vitamin C undernourishment.

The technique of Gothlin's method<sup>4</sup> essentially consists in the application of the cuff of a blood pressure apparatus to the arm for a period of fifteen minutes at a pressure of 50 mm of mercury and later of 35 mm of mercury. The number of petechiae appearing at the bend of the elbow (in a marked area of 60 mm) is counted. From this test he concludes that (for healthy members of the Nordic race), if a pressure of 50 mm of mercury for fifteen minutes does not produce more than four petechiae, the vitamin C standard is normal. If 50 mm of mercury produces more than eight petechiae or if 35 mm of mercury produces more than one petechia he deduces that the subject is not receiving a sufficiency of vitamin C.

Gothlin's experience with this test is a considerable one. In the spring of 1930 he found 18 per cent of a group of fifty healthy school children in the northern part of Sweden exhibiting a subnormal strength of the capillaries. Six of these children then had added to their diet one or two large oranges daily. Tests made a few weeks later showed "the capillaries to have attained normal or almost normal strength." On a closer analysis of these six cases, however, it is seen that at the end of the period when orange juice was given three of the cases showed negative capillary resistance tests, the fourth was on the borderline of normality (seven petechiae), the fifth showed an improvement but was still positive at the end of five weeks, and the sixth case became definitely worse.

Gothlin has ascertained the minimum antiscorbutic protective dose to be from 0.7 cc to 1 cc of orange juice per kilogram of body weight. The children that he studied had received from 60 to 120 cc of orange juice daily, an amount that is considered adequate protection against scurvy, and yet only 50 per cent of his cases showed by the capillary resistance test that they had responded to the treatment given.

In a later<sup>5</sup> and more extensive survey made in April 1931, of school children (in districts north of the arctic circle), it was found that the number showing positive capillary resistance tests varied in different localities from 5.9 to 21.5 per cent. It was ascertained that the children were receiving a diet poor in vitamin C.

Because of my interest in this subject I carried out at the Home for Hebrew Infants in February 1933 a study of a group of twenty-three healthy young children, ranging in age from 19 to 40 months. The children at this institution live under ideal hygienic conditions and their diet is carefully planned and supervised, due attention being given to adequate supple-

ments of antirachitic and antiscorbutic substances. Only such children were selected who at the time of examination and for a period of two months preceding this examination were free from any acute illness that might have influenced the strength of the capillaries. In making the capillary resistance test a pressure of 50 mm of mercury was used.

Of the entire group that were considered to have received adequate antiscorbutic protection, there were five who showed positive tests (21.7 per cent). In three of the positive cases an additional amount (60 cc) of orange juice was then given each day for a period of three weeks. At the end of this time two of the cases were still positive and one became negative. Only one observation was made before the administration of orange juice. A single observation is insufficient, as will be seen later from the variable results obtained when the same child is tested at different times.

However, in order to make this study more nearly comparable to that of Gothlin's group, I investigated a group of sixty-five older school children, ranging in age from 9 to 14 years, and about equally divided as to sex. These tests were begun in February 1933 and

continued at intervals of not less than fourteen days up to the end of the school year in June and then started again in October and terminated in April 1934. These children were mostly of Jewish extraction and exceedingly well nourished. Their diets included adequate amounts of fresh fruits, vegetables and milk. Without exception they stated that orange juice was part of the daily diet. In fact in the neighborhoods in which these children live a variety of fresh fruits and vegetables are to be had at all times of the year at the stores. There is no doubt, then, that these children were receiving a sufficient amount of the antiscorbutic vitamin in their dietary.

Of the sixty-five children studied it was found that six, or 9.2 per cent, showed a positive reaction to the capillary resistance test. The summary of these data in the positive cases is shown in the accompanying table (cases 1 to 6). The results show re-examinations in some of the cases at ten different times, whereas Gothlin retested his cases once and in two instances twice. The point that I wish to make is that the variation is so great from time to time that it is only by repeated testing that such differences can be demonstrated. These variations made it impossible for me to conduct the therapeutic test with orange juice which I had planned, because a period during which a positive reaction to the test was constant did not present itself.

<sup>5</sup> Falk G, Gedda K O and Gothlin G F. An Investigation of the Skin Capillaries and Indirectly into the Vitamin C Standard of School Children in the District of Norrbotten North of the Arctic Circle. *Uppsala Lakaref forh* 35: 1 1932.

At first I tested the capillary strength of one arm at each examination. In subsequent tests I observed the capillary strength of both arms each time. It is in this latter procedure that my technic differs from that of Gothlin, for he studied one arm each time. That this difference in procedure is justified may be seen from the table, which shows that more positive cases were obtained when both arms were tested than when one was tested alone. If the results obtained in case 3 are inspected it will be found that on eight occasions in which both arms were tested the result on the right side was positive only twice whereas it was positive five times on the left. Case 1 shows four positive tests on the left and three positive tests on the right. Case 4 never showed a positive test on the right side. Consequently I feel that had I not made tests on both arms some positive observations might have been missed.

If the number of petechiae observed in the eight positive cases are totaled, it is to be noted that there were almost twice as many on the left side as on the right. I cannot explain this difference satisfactorily.

I next studied a smaller group of sixteen malnourished school children (of about the same ages as in the first group) in one of the poorer sections of the city. The nationalities represented were Italian, Polish, Swedish and Jewish. The families were all getting home relief from the city. The physical condition of these children was far inferior to the other group. Their dietary was not generous and contained only a small supply of fresh fruits and vegetables at irregular intervals. In this group I found during December and January two positive cases (cases 7 and 8, 12.5 per cent), an incidence approximating the group of well nourished children.

#### COMMENT AND CONCLUSIONS

The integrity of the capillary vessel wall is affected by chemical and physical as well as nervous influences. Gedda's<sup>6</sup> investigation also shows a seasonal influence, for he found that the number of petechiae in May was almost double the number in September in healthy subjects. As pointed out by Dalldorf,<sup>7</sup> a consistent feature of the measurements of capillary resistance is the occurrence of differences between persons, and this constitutes a serious limitation to the use of the test. Hess, in his extensive experience with scurvy, found that there were decided individual variations in regard to the reaction to the test, so that "although it is true that petechial spots are far more numerous in individuals suffering from latent or active scurvy, the reaction cannot be used as evidence of a deficiency in vitamin C intake." My observations indicate a considerable variability in results when the same children were tested at different times.

From these studies which show a positive capillary fragility test in 21.7 per cent of a group of well nourished children of preschool age, and in 9.2 per cent of well nourished school children receiving abundant vitamin C supplements to their diet, and in 12.5 per cent of malnourished school children with a small supply of vitamin C, it may be concluded that a positive reaction to the capillary resistance test does not necessarily denote an insufficient vitamin C intake.

## A CRITICAL SURVEY OF THE RETINAL LESIONS IN CHRONIC GLOMERULAR NEPHRITIS

EDWARD W. CANNADY, M.D.  
AND

JAMES P. O'HARE, M.D.  
BOSTON

The large number of patients visiting the renal clinic of the Peter Bent Brigham Hospital during the past seventeen years has afforded an unusual opportunity for the observation of the progressive changes in the ocular fundi in cases of Bright's disease and for their correlation with clinical and laboratory observations. The majority of reports in the literature on the retinal manifestations of chronic glomerular nephritis have consisted of cases in which single or relatively few ophthalmoscopic observations had been made. The patients comprising this series have had frequent examinations over an average period of nearly four years.

It was our original purpose in this investigation to determine the prognostic significance of the severe retinal lesions of chronic glomerular nephritis. We soon found that our group of cases revealed information of even greater significance, several of the features differing from those previously reported by others. These concerned the incidence of the advanced retinopathies in chronic glomerular nephritis, the types of retinal manifestations accompanying this disease, and the pathogenesis of the various lesions.

We have selected from the many cases in the clinic thirty-two instances of chronic glomerular nephritis which presented no retinal lesions or only the minimal signs of retinal arteriolar sclerosis at the time of the initial examination. Patients showing evidence of advanced retinopathy when first examined, those not continuously observed until their death, and those dying from other causes than uremia are not included in this series. We believed that only this type of case would reveal accurate information concerning the development and course of the retinopathies accompanying a primary glomerular nephritis. Although the number of cases is relatively small, we consider the observations significant and the study somewhat unusual. Observations on each patient were made at frequent intervals over a period varying from six months to fourteen years. With few exceptions the examinations were made by one observer (O'H.). Furthermore, the clinical diagnosis of chronic glomerular nephritis was confirmed by autopsy in twenty-one cases, while in the remainder of the cases the essential features and course of the disease left no doubt as to the accuracy of the diagnosis.

#### METHOD OF INVESTIGATION

Twenty-one of the thirty-two cases of chronic glomerular nephritis which were selected for study were without retinal lesions of any sort when first examined. The essential features of this group of twenty-one are included in table 1. The remaining eleven cases of the series (table 2) were observed to present the minimal signs of retinal arteriolar sclerosis at the time of the initial visit to the clinic.

The average interval between visits of these patients to the renal clinic was three months. A few were seen

From the Medical Clinic of the Peter Bent Brigham Hospital. Aided by the Fund for Research in Renal and Vascular Diseases.

at less frequent intervals. The clinic visit included an ophthalmoscopic examination through dilated pupils, in addition to the usual physical examination, in analysis, and study of renal function. The same procedure of examination was carried out on these patients during periods of hospitalization.

We found that certain ophthalmoscopic pictures could be differentiated according to a few changes appearing in the papilla and retina, although the demarcation was not always clear in every case. An attempt was made to classify every retinal picture

of the larger arteries. Obviously not all these changes were found in every eye.

The group known as arteriosclerotic retinopathy, a term suggested by Fishberg,<sup>2</sup> includes those retinal lesions characterized by little or no involvement of the papilla, hemorrhages of various sizes and shapes, small "hard-white" spots in the retina, and the vascular changes of a marked arteriolar sclerosis. Arteriosclerotic retinitis,<sup>3</sup> choroidal arteriosclerosis,<sup>4</sup> and angiosclerotic retinitis<sup>5</sup> are the terms others have applied to this group of lesions.

observed, the cases being divided into the following four groups: (1) no lesion at all, (2) retinal arteriolar sclerosis, (3) arteriosclerotic retinopathy, and (4) hypertensive neuroretinopathy.

The type of lesion which we call retinal arteriolar sclerosis is similar in appearance to that described by Friedenwald.<sup>1</sup> It is characterized by irregular tortuosity of the small macular arterioles and those in the periphery of the fundus, caliber variations, fullness and tortuosity of the larger vessels and arteriovenous compression, and in the later stages sclerotic changes

The fourth group, called hypertensive neuroretinopathy by Fishberg,<sup>2</sup> comprises those lesions of the ocular fundi consisting of hyperemia, indistinct margins, occasional edema of the disk, arteriolar changes, retinal hemorrhages and retinal "white spots." Both the large "cotton-wool" spots and the small "hard-white" spots appeared in this group, although the

"cotton-wool" type predominated. This group of lesions has been termed renal retinitis,<sup>3</sup> albuminuric neuroretinitis<sup>6</sup> and the retinitis of nephritis.<sup>7</sup>

Arteriosclerotic retinopathy and hypertensive neuroretinopathy were formerly grouped together under the term "albuminuric retinitis," but since the early observation of Gunn<sup>8</sup> that albuminuria did not always accompany this form of retinitis, other names have been suggested and attempts made to divide the group into various subdivisions. The chief criteria we used in differentiating arteriosclerotic retinopathy and hypertensive neuroretinopathy were the appearance of the papilla and the types of white spots. In several cases it was difficult to decide on the proper classification, as characteristics of both types of lesions were present. This difficulty has led several observers to believe that no attempt should be made to separate the advanced retinopathies but that they should be considered as one group. We attempted to separate them, hoping to obtain from the retinal lesions alone a practical method for differentiating between the primary vascular and the glomerular changes in the kidney.

#### RESULTS AND COMMENT

Several pertinent facts can be gleaned from the tables. The average age of these patients at the time of the initial examination was 26 years, the youngest being 10 and the oldest 59.

In the entire group of thirty-two patients, only two failed to show fundus changes on repeated examinations. Five did not progress beyond the stage of arteriolar sclerosis. Eleven cases were classified later as arteriosclerotic retinopathy and fourteen as hypertensive neuroretinopathy.

The high incidence of retinal lesions in this series (thirty out of thirty-two) is at variance with the opinion of many others who hold that retinitis is not common in chronic glomerular nephritis. The series of 102 cases reported by Moore<sup>9</sup> included only twenty-four with definite retinitis. However, in a group of twenty uremic patients he failed to find evidence of a retinal lesion in only one. Moore notes that Miley found only fifty-two cases of retinitis among 166 cases of all types of nephritis and Elschnig forty-three among 199 patients. In fifty-five patients with chronic glomerular nephritis, Fishberg and Oppenheimer<sup>10</sup> found twenty-four with normal fundi.

We believe that the discrepancy between these reports and ours is due to the fact that few of these authors had the opportunity to observe their cases throughout the entire course of the disease. Our experience indicates that retinitis is extremely common in advanced chronic glomerular nephritis, and we believe that frequent observations during the entire course of the disease will reveal definite evidence of retinal involvement in almost every case.

#### TYPES OF RETINAL LESIONS

Twenty-eight of our cases were observed at a time when only the early signs of arteriolar sclerosis were present. Five did not show any extension of the lesions beyond these changes in the blood vessels.

There was, as one would expect, progressive increase in the degree of sclerosis involving these small vessels.

In twenty-five of the group of thirty-two cases advanced lesions of the fundus developed. The appearance of arteriosclerotic retinopathy in eleven of twenty-five patients who died in uremia has convinced us that this retinal picture is not confined to primary vascular hypertension. Furthermore, our figures demonstrate that the patients who had this particular lesion were no more or no less toxic at the time of development of the lesion than were the patients who showed hypertensive neuroretinopathy. This opinion is based on a comparison of the degree of nitrogen retention and anemia in each group. The results make us doubt the wisdom of attempting to divide the various lesions of the fundi into those of "renal" and those of "nonrenal" origin, as has been done by Moore,<sup>9</sup> Davies,<sup>11</sup> Cohen,<sup>12</sup> Benedict,<sup>13</sup> and others. We agree with Shaw, Clarke and Pitt,<sup>14</sup> the Friedenwalds<sup>15</sup> and Bulson<sup>16</sup> that there is no distinctive type of retinal lesion accompanying chronic glomerular nephritis.

Furthermore, our observations lend little support to the statement of Wagener,<sup>17</sup> Keith<sup>18</sup> and others that the fundi in "malignant" hypertension can be differentiated from those in glomerular nephritis. Neither the presence nor the absence of edema or anemia of the disk can be used to differentiate primary glomerular nephritis from secondary chronic vascular nephritis with or without the so-called malignant hypertension. Keith stated that the arteriolar lesions are unusual in the fundi of chronic glomerular nephritis, but thirty of our thirty-two patients showed definite evidence of these changes. The early arteriolar involvement was detected before the appearance of the other forms of retinopathy in all but two cases.

Another striking feature of this study was the progression in five patients of the retinal lesions from hypertensive neuroretinopathy into a late stage of arteriosclerotic retinopathy. These observations make us agree with Shaw,<sup>14</sup> the Friedenwalds<sup>15</sup> and Duke Elder<sup>17</sup> that the retinopathies under consideration are essentially only variations or stages of the same pathologic process. We are convinced that the attempt to make an ophthalmoscopic differentiation between the retinopathies due primarily to glomerular nephritis and those resulting from vascular hypertension is not only unwise but impossible in most cases.

#### PATHOGENESIS

The scope of this paper does not permit a detailed discussion of the pathogenesis of the advanced retinopathies, nor is such a discussion necessary, since this subject has been admirably covered by the recent reviews of Friedenwald,<sup>1</sup> Fishberg<sup>10</sup> and Volhard.<sup>15</sup> We will only attempt to indicate the correlation of our observations with those of others.

In our series the two patients who showed no retinal lesions on repeated examinations were essentially non-hypertensive throughout their entire course although one had a slight elevation of blood pressure during the last few days of life. Five patients never progressed beyond the stage of retinal arteriolar sclerosis, although there was some progression of the strictly vascular lesion. All but two of the twenty-five that eventually appeared with an advanced retinopathy were known to have previously passed through the stage of uncomplicated retinal arteriolar sclerosis. In these two cases the arteriolar changes and the other features of the advanced retinal lesion were noted simultaneously. The course of these two cases was very rapid and it is probable that more frequent observations would have revealed the changes in the retinal vessels before they were noted in the retina itself.

As indicated previously the picture of hypertensive neuroretinopathy changed to one of arteriosclerotic retinopathy in five patients. Such observations as those previously mentioned strongly suggest the primary nature of the vascular process, the development of the advanced retinal lesions being secondary to the primary vascular disease. According to this conception the two types of retinopathy are variants or different stages of one fundamental vascular process. Thus we believe to be the opinion of Friedenwald<sup>19</sup> and others.

Hypertension was the most common factor preceding or accompanying retinal changes in these patients. The blood pressure remained relatively low in the two patients who died without retinal lesions. We found that the diastolic pressure was of greater significance and that it was less variable than the systolic pressure. For these reasons the latter has been omitted from our discussion. In the twenty-one cases that showed no retinal lesions on initial examination, the initial diastolic pressure averaged 89 mm and sixteen presented an initial diastolic pressure below 91 mm. An average diastolic pressure for the series of thirty-two cases, when the uncomplicated lesions of retinal arteriolar sclerosis were first detected, was 102 mm. The hypertension preceded the appearance of the arteriolar changes in thirteen of the seventeen who were observed before these early changes were seen. A marked elevation in diastolic pressure was present in every case showing either of the two advanced retinopathies, the diastolic pressure in this group averaging 122 mm. The patients with hypertensive neuroretinopathy had a higher maximum diastolic blood pressure than those with arteriosclerotic retinopathy. The diastolic pressure in seven of the former exceeded 140 mm, while it did not rise above this level in any of the latter.

The information gained from this investigation agrees with the observations of many who believe that the advanced retinopathies seldom occur in the absence of hypertension and that the elevated tension precedes the appearance of the retinal lesions. Many observers contend that the factor producing the hypertension is the one which is responsible for the arteriolar changes appearing in the fundus. The absence of hypertension in the two patients in whom retinal lesions failed to develop and yet who died in uremia is very significant and indicates that the hypertension is of prime importance in the development of the retinopathies of glomerular nephritis.

There are some writers who remain unconvinced of the vascular nature of these lesions and who continue

to seek a toxin that may produce direct injury to the retinal nerve cells. They have attempted to correlate the retinal manifestations with evidence of nitrogen retention. The cases in our group who have shown nitrogen retention, low phenolsulphonphthalein excretion and secondary anemia accompanying the various ophthalmoscopic pictures give little comfort to the proponents of the theory of direct toxic action on the retina itself.

The frequent occurrence of retinal lesions in vascular hypertension and the appearance of the retinopathies in several of our patients before the blood urea nitrogen was greatly elevated lend additional support to the theory that hypertension and not retention of toxins is of prime importance in the development of retinal arteriolar sclerosis and the later manifestations of the advanced retinopathies.

We consider that the most convincing evidence of the hypertensive and vascular nature of the retinopathies is the fact that in every one of our cases of marked hypertension retinopathy developed. The only two patients who failed to show any changes in the fundi were those without a greatly elevated diastolic pressure. However, both of these patients had a high blood urea nitrogen many weeks before death.

#### PROGNOSTIC SIGNIFICANCE

The prognostic significance of the appearance of the advanced retinopathies in our series of glomerular nephritis does not differ from that reported by others. The maximum duration of life after the advanced lesions (arteriosclerotic retinopathy and hypertensive neuroretinopathy) appeared was twenty-three months, the average duration of life of the entire group was 6.3 months. Moore<sup>9</sup> stated that few live as long as two years and cited the figures of Miley, who found the average duration of life after the discovery of the retinitis to be but four months.

Since von Michel<sup>20</sup> stated in 1884 that the majority of patients with "granular kidney" complicated with retinitis die after a course of one and one-half years, the serious prognostic significance of these lesions has been recognized. The occasional reports of patients living beyond this period, however, indicate that in even so serious a condition the prognosis is not certain. Moore<sup>9</sup> reported that one patient lived seven years after the appearance of "renal" retinitis. Fishberg<sup>2</sup> called attention to the fact that of his patients one lived eight years and one of Leber's patients survived seventeen years after "albuminuric" retinitis had been discovered. We saw one patient with chronic glomerular nephritis who remained in fair condition for fourteen years after the detection of changes characteristic of a marked hypertensive neuroretinopathy.

#### SUMMARY

Thirty-two cases of chronic glomerular nephritis have been followed over a period varying from six months to almost fourteen years. In thirty of the cases, retinal changes developed before death. Twenty-five showed the picture of an advanced state of arteriosclerotic retinopathy or hypertensive neuroretinopathy.

An elevation in blood pressure preceded the appearance of retinal arteriolar sclerosis in thirteen of seventeen cases. Hypertension was present in every patient who had an advanced retinopathy. The blood pressure was low in the only two cases without vascular or other retinal changes.

<sup>19</sup> Friedenwald J. S. The Pathogenesis of Albuminuric Retinitis. *Lubman Annals*. Vols. 2: 453. 1932.

<sup>20</sup> von Michel. *Lehrbuch der Augenheilkunde*. Weisbaden. J. F. Bergmann. 1884.

The early signs of retinal arteriolar sclerosis preceded the advanced lesions in all but two cases. In these two cases the arteriolar changes and the other features of the advanced retinopathy were noted simultaneously. The picture of hypertensive neuroretinopathy changed to one of arteriosclerotic retinopathy in five cases.

Every patient in the group including even those with no retinal changes, developed marked nitrogen retention and died in uremia.

The average duration of life in our series after the appearance of either arteriosclerotic retinopathy or hypertensive neuroretinopathy was less than seven months, the maximum was twenty-three months.

#### CONCLUSIONS

1 In almost every case of chronic glomerular nephritis, retinal changes develop before death.

2 An ophthalmoscopic differentiation between the lesions of chronic glomerular nephritis and primary vascular hypertension is impossible in most cases. In chronic glomerular nephritis, both arteriosclerotic retinopathy and hypertensive neuroretinopathy may occur.

3 The occurrence of the two types of advanced retinopathy in the same patient at different times suggests that they are merely variants or different stages of the same pathologic process.

4 Hypertension is the most common etiologic factor in the production of the retinal arteriolar lesions. The arteriolar changes precede the development of the advanced retinopathies.

5 An advanced retinopathy in chronic glomerular nephritis usually indicates death within seven months.

## A DERMATITIS DUE TO ANILINE DYE IN A FOOD PRODUCT

### REPORT OF A CASE

HARRY LEONARD BAER, M.D.  
PITTSBURGH

The recognition of the existence of allergy in patients stimulates those interested in the causation of the condition to delve into the minutest details to obtain significant leads. Hunches and suspicions should be disproved before they are discarded. The method of approach and interrogation should be systematic. The following case is a striking example of the manner in which the coloring matter of a food product in common use can ultimately act as a sensitizing agent and produce toxic manifestations.

### REPORT OF CASE

Mrs H J, aged 44, in November 1933, presented an erythematous, maculopapular eruption confined to the neck, shoulders, arms and forearms on both the covered and uncovered areas. The eruption simulated erythema multiforme in certain areas, while in the areas where scratching had occurred it resembled subacute eczema with scaling. Some areas presented an evanescent, urticarial type of lesion. The eruption had been present at various intervals for the past six months.

Nausea and abdominal cramps were noted anywhere from two to three hours after meals and at times there was diarrhea. The past history, physical examination and laboratory tests presented nothing of significance. There was no history of allergy nor was there any history of the ingestion of drugs.

From the Pittsburgh Skin and Cancer Foundation

Mild protective lotions had relieved the condition. An attempt to eliminate either an external or an internal factor as the etiologic agent was of no avail. A careful scrutiny of her diet did not reveal any suspicious food. It was assumed after several weeks of study that cleaning fluid was the factor for she stated that the onset of the condition dated to several days after she had worn garments that had been cleaned. A patch test of the cleaning fluid, applied to the forearm produced an erythema that persisted for forty eight hours. The tests were negative on two individuals who served as controls.

The patient returned in March 1934 with a recurrence of the condition distributed as it had been the previous November. It had been present for two weeks. No new or cleaned garments had been worn. During the interim between the first and second visits to the office, the eruption had been present but it was not sufficiently annoying to cause her to seek advice. At this time an acute and subacute dermatitis of a nondescript character was present. Nausea and abdominal distress, with diarrhea about three hours after meals, were noted.

She was carefully questioned in an effort to obtain a clue to the possible exogenous or endogenous cause of the condition. Nothing of importance was learned until the patient volunteered the fact that she had confined her diet to vegetables and especially to salads of vegetables and fruits in gelatin, colored with a green solution. She ate the salads at least once or twice a day. The vegetables themselves or the insecticides sprayed on them during their growth were ruled out as the cause by elimination of the vegetables from the diet. Skin tests (intracutaneous) were entirely negative for food stuffs. Finally, the green coloring matter was placed under suspicion. This dye was prepared by Joseph Burnett Company, Boston, Mass. and the attached descriptive brochure stated that it contained 26 per cent certifiable aniline color. The green coloring matter was eliminated from the diet and within three weeks the condition had cleared up. The gelatin with the green coloring matter was returned to the diet and the dermatitis recurred in eight days, together with abdominal cramps soon after eating. The dermatitis was permitted to clear and a salad made with gelatin without the coloring matter has been used ever since without a recurrence. Patch and passive transfer tests were negative. The period of observation for the patch tests was six weeks, as Sulzberger<sup>1</sup> and Ingram<sup>2</sup> have stressed the fact that patch tests may not be positive for from several days to six weeks or longer.

### COMMENT

Many synthetic dyes have been placed under suspicion as irritants to the skin. However, the majority of the pure synthetic dyes in themselves are innocuous to the skin. In the process of dye making, strong acids and alkalis (particularly lime) are used to convert the benzene, toluene, naphthalene, benzidine and similar substances into the finished dyes. The injuries listed are produced in handling or dealing with the various stages of the "crudes," "intermediates" and "color making" (manipulation of the intermediates). Various observers have reported conflicting data regarding the number of individuals who have been affected in the various stages of dye making. Bachfield<sup>3</sup> generalizes the position by stating that the farther the process advances from the crude state the less the toxicity.

The types of dermatoses listed as produced by the various stages in dye making are quite varied. There is a marked difference in the resisting power of the individual skin. The texture of the skin is an important determining factor in the susceptibility, but the activity of the agent is of prime importance.

The necessary amount of the dye and the length of time it has to be used before it will show toxic effects

1 Sulzberger M B and Wise Fred Drug Eruptions (Dermatitis Eczematosa Due to Drugs) Arch Dermat & Syph 28 461 (Oct) 1933  
2 Ingram J T Dye Dermatitis in Relation to Idiosyncrasy Brit J Dermat 44 422-426 (Aug Sept) 1932  
3 Bachfield quoted by White<sup>4</sup> p 382

are not known. It is generally supposed that the constant use of any antigenic substance (sensitizing agent) over a definite period of time will sooner or later affect the individual.

Prosser White<sup>4</sup> states that ingestion of the aniline dyes will at times produce gastric symptoms. He lists the various dermatoses that develop in the process of the dye industry, and they are mostly produced by contact.

Ingram<sup>2</sup> states that 4 per cent of normal individuals show a natural idiosyncrasy toward the phenylenediamines.

The synthetic organic dyes derived from aniline have been in use since 1883. McCafferty<sup>5</sup> states that from 1 to 2 per cent of individuals are susceptible to the toxic effect of aniline. It is toxic for animals and will kill in small doses. In human beings it has produced gastric symptoms, anemia, loss of weight and temporary loss of vision.

Weyl<sup>6</sup> states that the aniline and azo dyes are neither toxic nor irritant in themselves but they may inaugurate irritation. Certain of them rubbed into the skin or injected into the subepithelial tissues can produce a proliferation of the epithelial structures in various degrees and may even cause a verrucous overgrowth. This fact has been known in the use of scarlet red, amido-azotoluene-betanaphthol and brilliant red, for promoting epithelization.

Sachs<sup>7</sup> states that the majority of these drugs can be administered orally without toxic effects.

The culinary art has employed the enhancement of the appearance and color of foods to increase the gustatorial effect. The vegetable dyes have been used for this purpose but recently on account of the fastness of the color, aniline dye has been substituted. Only a small percentage of the dye is used, but nevertheless the fact must be recognized that sensitivity or toxicity may be caused. The reported case is illustrative of the production of sensitivity and toxic gastro-intestinal effects by the coal tar derivative.

The question is raised as to whether the reaction produced by the aniline dye in this patient is truly toxic or whether it is allergic. If the patient is reacting abnormally to small doses of a common allergen, then the manifestation is allergic. But the possibility that the gastro-intestinal symptoms are truly toxic cannot be definitely excluded. A truly toxic reaction as produced by such substances as mercuric chloride and mustard would cause an immediate gastro-intestinal upset with vomiting, but these irritants are more concentrated than the one in the case under discussion. The response of the patient to the aniline dye was a general one, not based on an idiosyncrasy, hence it was a toxic rather than an allergic reaction. The procedures that are used to demonstrate allergy (passive transfer, scratch, patch, and intradermal tests) were entirely uncorroborative.

The toxic effects of the aniline derivative cannot be entirely dismissed. The fact that the oral administration of the aniline dyes will produce a varying amount of toxic symptoms is generally admitted in the literature. The individual will respond with symptoms, based on his tolerance and not dependent on previous sensitization with small tolerating doses. This reaction

may be regarded as similar to the gradual development of a sensitivity to drugs such as arsphenamines, amodopyrine and quinine. I believe that over a protracted period this patient has become sensitized to the aniline dye in a manner similar to the development of idiosyncrasy after exposure to the hair and fur dyes in cases reported by Ingram.<sup>2</sup>

#### SUMMARY

In a case of sensitivity to a green coloring matter (an aniline derivative), speculation arises as to whether it presents a true allergic reaction or a true toxic manifestation of the drug. The point to be carried is that the aniline derivatives used as dyes in food-stuffs can produce both a dermatitis and gastro-intestinal symptoms. Interest is aroused not only by the natural sensitivity of a patient to such a dye but by the ease with which the sensitivity can be acquired.

## MESENTERIC VASCULAR OCCLUSION WITH RECOVERY

JOHN R. GREEN, M.D.

AND

CHARLES H. ALLEN, M.D.

INDEPENDENCE, MO.

The high mortality rate encountered in cases of occlusion of a large branch of the superior mesenteric vessels whether by embolism or thrombosis has made surgical treatment appear futile. Bassler<sup>1</sup> quotes Cabot as saying, "Surgery has little or no business here." Thrombosis treated surgically, is believed to be more fatal than embolism because of its progressive nature tending to involve the entire superior mesenteric artery or veins and produce certain death. Most of the cases that have ended in recovery have been cases in which operation has been done early, but under the most favorable conditions a mortality rate approximating 90 per cent is the best that has been reported.

The patient here described was operated on four days after the onset of symptoms. A late diagnosis in an abdominal disaster is never a source of pride. A large number of cases of mesenteric vascular occlusion will be diagnosed late, so long as a decent conservatism is maintained, which keeps the surgeon from opening the abdomen in cases of early pneumonia, coronary arterial disease, tabetic crisis and endocrine and allergic disorders.

Trotter<sup>2</sup> analyzed 360 cases of mesenteric vascular occlusion reported in the literature to 1913, and in only thirteen instances was a preoperative diagnosis made. Larson,<sup>3</sup> in 1931, published an important contribution, based on a review of thirty-six cases in which necropsy was performed. He quotes Kussmaul and Gerhardt<sup>4</sup> concerning the conditions that should be present to justify a diagnosis of this disease and notes that the criteria of these authors agree closely with phenomena observed in his series: (1) a source of an embolism, (2) melena, not to be accounted for by a primary intestinal lesion, (3) rapid and excessive fall of temperature, (4) severe colicky abdominal pain, (5) later,

<sup>2</sup> Trotter L. B. C. quoted by Larson<sup>3</sup>.

<sup>3</sup> Larson L. M. Mesenteric Vascular Occlusion. Surg. Gynec. & Obst. 53: 54 (July) 1931.

<sup>4</sup> Kussmaul and Gerhardt quoted by Larson<sup>3</sup>.

distention of the abdomen with tympanites and shifting dullness, and (6) embolic phenomena elsewhere in the body

Loop<sup>5</sup> describes the following group of symptoms as a characteristic syndrome of mesenteric vascular occlusion. He says "Sudden violent abdominal pain, not markedly localized, persistent vomiting usually diminishing after the first few hours, slight or moderate fullness of the abdomen without muscle spasm and a dull percussion note. The phlegmatic cases are much less clear in their evolution. There is vague abdominal unrest with occasional vomiting, unrelieved by fairly satisfactory bowel movements and without localized tenderness."

These authors, I believe have drawn a clear picture of this baffling disease, but many patients are certain to be operated on late.

#### REPORT OF CASE

A woman aged 24, a graduate nurse, had been married for one year. There was no history of pregnancy or pelvic inflammatory disease. An appendectomy was done in July 1933, and an uneventful recovery followed. A mild cystitis was present for about one month after the operation. A period of excellent health, during which time the patient served as a private duty nurse and did her housework was terminated by the sudden onset of the present illness, March 15, 1934. She had eaten her evening meal with her usual good appetite. While washing dishes, she was suddenly seized with a violent epigastric pain. She took three glasses of soda water and began vomiting. She took an enema with the same results. The bowels had moved twice that day. The pain gradually spread over the entire abdomen. One of us (C H A) was called at midnight and gave her one-fourth grain (0.064 Gm) of morphine. She rested fairly well during the night but the pain recurred in the morning and was continuous, accompanied by nausea and vomiting. We saw her together about 2 p m, March 16. She looked quite ill. The temperature was 99.4 F. The pulse rate was 90 with a good quality. Physical examination of the lungs was negative. The cardiologist, Dr. Thomas Twyman reported that the heart was normal. The abdomen was flat, rigid and tender in the lower portion, the entire upper part of the abdomen showed almost normal relaxation. The rectal examination was negative. The vaginal examination showed normal pelvic organs, except for the fact that the region about the left vaginal vault was somewhat tender, and an indefinite boggy mass was palpated high on the left side. The patient was sent to the hospital. The laboratory report showed 4,220,000 red blood cells and 13,000 leukocytes which rose to 25,000 in a few hours. A trace of albumin and a large amount of pus were present in the urine. Supportive treatment was instituted with only small quantities of water by mouth. She improved for twenty-four hours. During the third night after the onset of the trouble she grew worse. The pulse rate rose to 150, becoming weak and thready. This we interpreted as indicating an internal hemorrhage probably a ruptured abdominal pregnancy. Donors were obtained for a blood transfusion and the operation was done as soon as possible. Bloody, foul-smelling fluid was found in the abdomen and a straightened black segment of bowel was found lying in a vertical position slightly to the left of the spinal column. This corresponds to descriptions by Mall and Piersol<sup>6</sup> of the upper part of the lower two fifths of the jejuno-ileum. The pelvis was explored only for a probable extra-uterine pregnancy. The organs appeared normal except for blood and fibrin which were not associated with a tubal pregnancy. The decomposed mass about the black mesentery made it impossible to determine whether an abdominal pregnancy had been responsible for the interruption of the circulation in the mesenteric vessels.

The bloody purulent material was cleared away and the gangrenous bowel and mesentery were isolated with gauze packs. A fair margin of living bowel was clamped by a Payr clamp on both the proximal and the distal part, and cut with a cautery. The stumps of the mesenteric vessels were ligated, the dead tissue was trimmed away and the V-shaped gap was closed. The Payr clamps were carefully placed on the abdomen as in the Rankin<sup>7</sup> obstructive resection method in operations upon the colon. Special care was taken to observe that the distal and proximal ends of the bowel were in a favorable position, for protection of the bowel segments, and to make certain that the open bowel ends did not lie over mesenteric blood vessels or large abdominal blood vessels. The pathologist reported that there was a resected piece of small intestine 40 cm long. The entire wall was dark bluish red and necrotic.

The wound was left wide open. The intestine was held back with the fingers and gauze packs of ordinary operating sponge folded to a width of 2 inches were placed 1 cm under the parietal peritoneum all around the wound. The center was filled snugly but not tight enough to injure the two pieces of bowel or to cause pain. The gauze packing was washed out with 1 per cent chlorazene solution for three days. Then it was gently removed under nitrous oxide anesthesia and replaced with fresh gauze. The Payr clamp was removed from the proximal bowel end after thirty-six hours. The distal clamp was left on indefinitely. The bowel tended to move downward, the proximal end becoming slightly longer and the distal end retracting. After the ends of the bowel were opened rubber tubes were placed in the upper and lower openings for the purpose of transferring the bowel contents from the upper to the lower division and giving nourishment and water into the lower part of the bowel. Some of this was collected, filtered and placed in the distal segment of the bowel.

The wound was treated in this manner for five weeks. It presented a uniformly granulating surface. The general condition became good and a lateral anastomosis was done at the end of the fifth week. The peritoneal cavity was closed, also as much of the granulating abdominal wall was closed as possible. A blood transfusion was done after the primary and secondary operations. Few adhesions or little peritoneal damage was encountered aside from the damage to the exposed ends of bowel by feces and antiseptics. Moderately severe diarrhea followed for about ten days, then the bowel action became normal and general improvement was rapid.

#### COMMENT

No one surgeon encounters a large series of cases of mesenteric vascular obstruction. Such cases always occur suddenly and unexpectedly. This single case illustrates as well as a long series an application of the principles of modern surgery in treatment of the condition, and furnishes a method for lowering the mortality rate. Essential principles in the treatment of mesenteric vascular occlusion are as follows:

1. Action should be prompt, but not hasty beyond the point of understanding. The cases in which operation is done early have an almost prohibitive death rate. Charles H. Mayo<sup>8</sup> recently noted Ochsner's advice that with a moribund patient the operation for acute appendicitis should be delayed for from one to three days, "until the condition becomes subacute. When the thin streptococcal peritoneal fluid had had two days' time to fill with billions of leukocytes which destroyed their quota of bacteria and remained as pus cells, and immunity had been established with the walling off of the abscess, operation could be more safely performed." This advice is good in regard to almost any intra-abdominal lesion in which there is no continuous internal hemorrhage, perforation or torsion of the bowel.

6 Piersol, G. A. Human Anatomy. Philadelphia J. B. Lippincott Company, 1907.

7 Rankin, F. W. Resection and Obstruction of the Colon (Obstructive Resection). Surg. Gynec. & Obst. 50: 594-598 (March) 1930.

8 Mayo, C. H. The Influence of Pain and Mortality in Modern Medical Practice. Collected Papers of the Mayo Clinic 23: 1025 1931.

2 The multiple stage operation should be the rule in all late cases of mesenteric vascular occlusion as it is in many other critical abdominal conditions such as in cancer of the colon and in operations on the prostate gland. This type of operation gives the body time to gain a metabolic balance which may be an important factor in combating the disease, especially the thrombotic type of disease.

3 Peritoneal drainage must be adequate, if drainage is used at all. Horsley<sup>9</sup> has pointed out the need for reversal of the lymph current which protects the lymph and blood streams from overwhelming doses of foreign toxic substances. Many a case of sepsis is lost owing to lymphangitis caused by attempts to suture a wound in which drainage is necessary.

4 The obstructive resection method of Rankin has a stabilizing effect on the circulation of blood and lymph in the wall of the bowel and helps to control peristalsis. It avoids the disappointing effect of immediate enterostomy in acute peritonitis.

5 Blood transfusions, the maintaining of as good nutritional conditions as possible, the establishing of normal levels of chlorides and dextrose and the securing of an adequate water balance will help to make late cases of mesenteric vascular occlusion less formidable.

## INVOLUTIONAL MELANCHOLIA

### PROBABLE ETIOLOGY AND TREATMENT

AUGUST A. WERNER, MD

GEORGE A. JOHNS, MD

EMMETT F. HOCTOR, MD, C. C. AULT, MD

LEWIS H. KOHLER, MD

AND

MATTHEW W. WEIS, MD

ST. LOUIS

Great diversity of opinion exists in the minds of most neuropsychiatrists as to the status that should be accorded involutional melancholia as a clinical entity. As with most types of psychoses, no one has yet demonstrated a single direct or specific cause for this mental illness.

Strecker and Ebaugh<sup>1</sup> say

Involutional melancholia is probably a subdivision of manic-depressive but by virtue of its distinctive symptomatology its lengthy course and its association with a definite physiological life epoch (climacteric) it merits separate description. The present state of our knowledge only permits the statement that the climacteric and the widespread changes induced are in some sense causal factors but as to the exact mechanism there is very little definite information.

Henderson and Gillespie<sup>2</sup> in their textbook attempt to define the condition by giving a description of the signs and symptoms as found in this mental disease, without offering any specific etiologic factor as causative.

Noyes<sup>3</sup> in his latest book says

The question as to whether a distinct place in any classification of mental diseases should be accorded to involutional

melancholia has been the occasion of much discussion. Many psychiatrists have considered that the symptom complex known by others as involutional melancholia should be looked upon as a modified manic depressive psychosis occurring at a particular physiological epoch. In addition, however, to its effective characteristics there are special physiological factors of such dynamic importance and so peculiar to that period of the individual's life during which the mental disturbance occurs that separate consideration is justified.

Others associate the condition with presenile and arteriosclerotic change.

### ETIOLOGY

That this type of mental aberration occurs in both sexes is recognized by all neuropsychiatrists, the proportion given being approximately 3/2. The age incidence is earlier in women than in men, occurring between 40 and 50 years in the former, and usually after 50 years in the latter. The consensus is that involutional melancholia constitutes between 3 and 4 per cent of all mental disease. Most writers agree that no acceptable organic pathologic changes of the central nervous system have been demonstrated.

There seems to be a failure of these patients to adjust themselves to the stresses and strains incident to this period of life, when the endocrine glands, especially the reproductive glands, decline in function with consequent changes in the chemical, metabolic and vegetative activities of the body.

Noyes<sup>3</sup> says

In a significant number of cases of involutional melancholia we find a certain general type of personality make-up and of habits of life. A review of the patient's previous personality and temperament often shows that he has been an inhibited type of individual with a tendency to be serious, rigid, lacking in humor and overconscientious. Often his routine of life has been narrow, somewhat stereotyped, and devoid of diversions. Frequently he has been a loyal subordinate, meticulous as to detail, rather than an aggressive confident leader. Adjustments to new situations and circumstances are no longer easily made. Perhaps life has not brought either the success or satisfaction that hope has cherished. Regrets and a sense of failure contribute to the prevailing mood.

While the foregoing opinion is no doubt true and applies to many of these individuals, a more fundamental causative factor probably exists which unbalances these patients and allows this mental disorientation to manifest itself.

We believe that we have secured sufficient evidence by controlled clinical research to justify our belief that involutional melancholia yields to endocrine treatment, thereby giving presumptive evidence for accepting an endocrine basis for this condition.

### BASIC THEORY FOR RESEARCH

Zondek and Aschheim,<sup>4</sup> and Smith<sup>5</sup> proved the presence of a gonad-stimulating hormone of the anterior hypophysis by the production of graafian follicle development, sexual maturity and the formation of corpora lutea in immature white rats and mice within from three to five days by the subcutaneous introduction of anterior hypophyseal tissue.

Meyer, Leonard, Hisaw and Martin<sup>6</sup> demonstrated the inhibitory influence of theelin and ammotin on the

gonad-stimulating complex of the anterior pituitary of castrated male and female rats

The anterior pituitary has three important types of cells namely, chromophobe, eosinophil and basophil. Difference of opinion exists as to the importance of the chromophobe cells. Biedl believes that they are the precursors of the eosinophil and basophil cells. Others are of the opinion that only the basophil cells are derived from this source. It is known that following castration, hypertrophy of the anterior hypophysis occurs. Castration causes the appearance of two histologic changes in the anterior pituitary, namely (1) cells of castration which are two or three times the size of the normal cells found in this gland and (2) a relative increase in the size and number of the eosinophils. Following castration, no more follicular hormone is produced, thereby removing the inhibitory effect of this substance on the anterior pituitary, probably allowing it to overact.

Fluhman<sup>7</sup> has devised a modification of the Aschheim-Zondek test by the use of the patient's blood serum to determine the quantitative amount of anterior lobe gonadotropic hormone present in women having various types of menstrual abnormality or absence. He has found an increased amount of gonadotropic hormone in the blood serum of most of the castrates and women in the menopause whom he examined. The presence of an increased amount of gonadotropic hormone in these cases would seem to indicate that the menopause is due not to absence of gonadotropic hormone of the anterior pituitary but to failure of the ovaries to respond to further stimulation at this period of life. This failure of ovarian response at the climacteric precludes the further elaboration of the ovarian follicular hormone. With the absence of the ovarian

patients. A study was made of the symptoms as complained of by forty castrates and ninety six women in the menopause.<sup>8</sup> The object of this study was to correlate the symptoms of the two types of patients and to determine their degree of regularity of occurrence with the possibility of attributing these symptoms pri-

marily to the absence of the ovarian follicular hormone. Werner and Collier<sup>9</sup> have shown in two experiments in which thirteen castrate women were treated, that theelin is completely effective in relieving the symptoms that result from castration, again indicating that the absence of the ovarian follicular hormone primarily initiates this train of symptoms. Secondary to the absent or decreased follicular hormone there is disturbance of function of the "master" gland, the anterior pituitary, the thyroid, the suprarenals and the like, with a consequent imbalance of the delicate equilibrium normally existing between the two divisions of the autonomic nervous system. These symptoms have been classified by Werner<sup>8</sup> as nervous, circulatory and general. Tables 1, 2 and 3 will show the remarkable parallelism of their occurrence. Table 4 gives the order of frequency of these symptoms in the combined 136 cases.

While these symptoms have been considered and discussed individually in the original article, space will not permit such an analysis here. Table 4 will show that 96.3 per cent of the 136 patients studied complained of intense subjective nervousness, 76.5 per cent were excitable and 64.4 per cent showed marked irritability. Along with these nervous symptoms 26.7 per cent of the patients had a definite mild psychosis, characterized by mental depression, loss of interest in the ordinary activities coincident with their past life, decreased memory and ability for mental concentration, and frequent intervals of crying for no good reason.

follicular hormone there is amenorrhea, regression of the secondary sexual characteristics, characterized by loss of genital hair and atrophy of the external genitalia, the vagina and the uterus, with decreased mucous secretion and atrophy of the breasts.

Along with these objective signs there occurs a train of subjective symptoms that is distressing to many

7 Fluhman C F. The Significance of Anterior Pituitary Hormone in the Blood of Gynecologic Patients. Am J Obst & Gynec 20:1 (July) 1930.

at all. This condition if untreated or unimproved, may progress to anxiety psychosis in which the patients feel ill at ease. They have a fear of impending danger which they cannot explain. They worry unnecessarily and feel that something dreadful will happen to themselves, their loved ones or others. At times they imagine that some one is watching them or that they hear strange noises. I have had patients in the menopause develop persecutory delusions and some whose past life had been rather Bohemian develop in extreme religious outlook. Many times they have stated that if some relief were not given them they would lose their minds and have threatened self destruction.

Many physicians who have taken care of women at the climacteric have had this experience with their patients. This state of condition is not uncommon and might be called premenopausal psychosis and it is only one more step beyond this line to true involutional melancholia.

From an experience of having treated great numbers of these women over a period of twelve years, with marked relief from their distressing symptoms, a conviction was engendered that the more unfortunate institutionalized patients should derive marked benefit from administration of the more potent hormone, theelin.

#### METHOD OF PROCEDURE

This experiment is being conducted at the St. Louis City Sanitarium and at Missouri State Hospital No. 4, Farmington, Mo., where a combined series of forty-one patients with involutional melancholia are under treatment and observation.

To obviate the objection of some physicians who state that involutional melancholia is a psychosis and that these women would recover if physiologic solution of sodium chloride had been injected, so long as the patients thought that something was being done,

TABLE 5—Results of Technic in Therapy and Control Cases

Therapy Cases (Theelin 1 cc Intramuscularly Daily)

they were paired, and one half of the number were given 1 cc of theelin<sup>10</sup> intramuscularly daily, and the controls were injected with 1 cc of physiologic solution of sodium chloride daily. So that an honest and fair comparison of the results of treatment could be had, the patients were paired as nearly as possible according to the severity of their mental condition. In other words, they were classified and paired as having excellent, good, fair or poor chances for recovery.

<sup>10</sup> We are indebted to Parke Davis & Co for donating a generous supply of theelin to carry on this work.

Treatment was begun at Missouri State Hospital No. 4, Dec 21, 1933, on twelve patients. One half of these patients were given theelin and the other half were given physiologic solution of sodium chloride. A little later, as table 5 will show, five more patients were added to the list. May 9, 1934, the original

\* The figures indicate the number of women who complained of each individual symptom and who were or were not relieved of that symptom.

twelve patients had received injections daily for a period of 140 days, or twenty weeks. The last five patients on the list were treated for a shorter length of time.

Table 5 shows the results obtained with theelin and the failure to obtain results by the use of physiologic solution of sodium chloride. Table 6 lists the symptoms and some of the signs complained of and found during the original diagnostic survey of these patients. It will be seen that these symptoms are the same as those complained of by castrates, by women having ovarian hypofunction and by women during the menopause. The figures indicate the number of women who complained of each individual symptom and the number of women who were or were not relieved of each symptom during treatment.

A similar experiment is being carried out on twenty-two women having involutional melancholia at the St. Louis City Sanitarium, with one half of the number being used as controls. Since they have been treated for only approximately three months, insufficient time has elapsed to include them in this report. However we might state that their records show that of the theelin-treated women, one shows marked

improvement, four show moderate improvement, four show slight improvement and two show no improvement as yet. Of the controls, three show slight improvement and eight show no improvement.

The diagnosis of involutional melancholia in these patients and the opinion as to improvement or failure of improvement was made by the hospital staffs.

## COMMENT

As regards prognosis Noyes<sup>3</sup> is of the opinion that about 40 per cent of patients with involutional melancholia recover. Convalescence, however, is slow and those who recover are frequently ill for two or three years. Strecker and Ebaugh<sup>1</sup> state that authorities differ somewhat as to prognosis. The recovery rate is placed at from 23 to 40 per cent.

The treatment recommended by leading writers is of a negative nature, such as guarding the patient against self destruction, rest and quiet, sufficient sleep, maintenance of strength by nourishing food, and sedatives for nervousness and agitated states.

The treatment as outlined is necessary but does not strike at any specific cause of the condition. The use of theelin in involutional melancholia, we believe, is a rational procedure, as the results seem to indicate. The dosage of 1 cc of theelin daily was decided on arbitrarily. We feel that larger dosages would produce more rapidly beneficial effects. Werner and Collier<sup>9</sup> have shown that the clinical results obtained by theelin administration are dependent on the size of dosage and the duration of administration. The time element is an important factor in recovery. While apparently remarkable response is had within the short time of one or two months in an occasional case, this is not the rule. When a favorable response is manifested the improvement is gradual and continuous, in contrast to the apparent slow improvement and regressions of patients previously treated palliatively and expectantly. Cases showing marked improvement are kept in institutions with difficulty, for the patients wish to return home when they feel more normal and the relatives are anxious to have them at home for obvious reasons. When these patients become more rational, it is the consensus that most of them will do better under normal routine home life. However, their supervision and treatment with theelin should be continued at home under the care of the family physician for a period of one or two months after being symptom free to assist stabilization. If, after the patient has been off treatment, the condition should give evidence of recurrence, treatment should be reinstituted to prevent a relapse to the previous degree of mental incapacity. It might be well to give theelin to women who manifest severe menopausal symptoms and not wait for the more serious mental illness to overtake them.

## CONCLUSIONS

Forty-one patients with involutional melancholia are being treated from an endocrinologic point of view. Twenty-one of these women are being given 1 cc of theelin intramuscularly daily. The others are being used as controls but will be given theelin later.

The improvement in the theelin-treated patients has been greatly accelerated by the use of this hormone.

The more rapidly beneficial results obtained in the theelin-treated patients seems to indicate that the administration of this hormone is rational and strikes at the fundamentally causative factor.

## HERNIA INTO THE UMBILICAL CORD, CONTAINING THE ENTIRE LIVER AND GALLBLADDER

SUCCESSFULLY TREATED SURGICALLY

W. AUGUST NIEBUHR, MD

WAUKESHA, WIS

C. A. DRESCH, MD

CASSOPOLIS, WICH

AND

F. W. LOGAN, MD

MISHAWAKA, IND

Hernia into the umbilical cord is relatively uncommon. When it does occur, the contents are as a rule loops of intestine. Finding the liver and gallbladder, however, as congenital umbilical hernia contents, seems to be exceedingly rare. Such a case came under our observation, and a successful operation was done twenty-one hours after birth. The extreme rarity of such malformations and the fact that surgical care was successful, warrant this report.

These cases are considered to be due to faulty embryologic development. A brief reference to the subject of embryonic maldevelopments will be pertinent. Bardeen says<sup>1</sup>

In studying the variations of structure found in any part of the body it is of importance to distinguish the less variable from the more variable features. As a rule, the less variable features are associated with fundamental processes occurring early in ontogenetic development, the more variable features with processes of growth and differentiation occurring later in ontogenetic development. Thus while it is comparatively rare to have variations in the number of digits, finger prints are specific for each individual.

In the development of the human intestines three fundamental loops are formed. First the enterocolic which extends forward into the umbilical cord and is supplied by the superior mesenteric artery. Second, the gastroduodenal, which projects to the right at the base of the enterocolic loop and is supplied chiefly by a branch of the celiac artery. Third, the left colic, which projects to the left at the base of the enterocolic loop and is supplied by the inferior mesenteric artery.

The enterocolic loop undergoes normally an elaborate development and gives rise to the distal part of the duodenum, the jejunum, ileum, cecum, ascending colon and the right half of the transverse colon. The center of the base of the mesentery of this loop becomes fixed at an early period and seldom varies in position. The loop itself shows frequent variations in development, some of a fundamental character, others slight.

The gastroduodenal loop is simple and seldom shows fundamental variations, although individual differences in form in the adult are frequent and well marked. Primatively it is of a simple U form. Such variations as are found in the adult seem to be due in the main to variations in the development of the enterocolic loop.

The left colic loop, although it begins its development considerably later than the other two primitive loops, appears to be nearly as constant in formation. From it develop the left half of the transverse colon, the splenic flexure, the descending colon and the sigmoid colon.

From this it is apparent that the enterocolic loop may show frequent variations, fundamental or slight. The other two loops (gastroduodenal and left colic), however, seldom produce variations. Those of the gastroduodenal consist primarily of variations in the position of the stomach, and it is this loop with which we are here concerned, since the liver anlage grows out from it.

<sup>1</sup> Bardeen, C. R. Critical Period in the Development of the Intestines. *Am J Anat* 16: 427 (Sept.) 1914.

Bardeen<sup>2</sup> of the University of Wisconsin says further

During the third month of intra-uterine development there is normally a hernia of the intestines into the umbilical cord giving rise to the "umbilical loop," the loop supplied by the superior mesenteric artery. The loop then returns, apparently somewhat suddenly, to the abdominal cavity and undergoes the well known twist of the large about the small intestine. The subdiaphragmatic part of the alimentary canal above the umbilical loop constitutes the gastroduodenal loop. From it the liver and pancreas grow out. This portion of the gut has two mesenteries, a vertical and a dorsal, the liver growing into the former, the pancreas into the latter. Normally during embryonic development this portion of the gut and attached glands are so well fixed in place by these mesenteries that no umbilical hernia takes place. If the diaphragm fails to develop there may be a diaphragmatic hernia on one side or the other. An umbilical hernia of the gastroduodenal loop must be very rare.

Fig 1—Appearance at the age of 3 months. The ventral hernia with the scars of both incisions is clearly visible. The child is dehydrated, owing to a gastro intestinal illness from which it completely recovered.

#### REPORT OF CASE

The mother was delivered after a moderately long labor, of a son, her second child. The first child was 15 months old and was well. The mother, aged 19, and the father, 22, had always had good health. There was no history of congenital malformations in either branch of the family.

Aside from its evident deformity, the infant seemed normal at birth. Bowel movements were normal and there were no untoward symptoms until about 1 p. m. of the first day, when intermittent vomiting of moderate amounts of greenish fluid began. After consultation it was decided to send the infant to the hospital for possible surgical intervention.

Examination eighteen hours after birth revealed that the infant was well developed, weighing 6½ pounds (2,950 Gm), and was normal except for the umbilical cord stump which was approximately 13 cm in length, containing an ovoid mass, about the size of a small and somewhat flattened orange, in the base of the cord. About 5 cm distal to the mass the cord had been ligated and was cut 2 cm beyond the ligation. The diameter of the cord proximal to the ligation was 4 cm. The

cord itself was a whitish gray and the surface was dull. Palpation revealed a relatively firm, immovable, smooth mass, without indentations such as one might expect to find where loops of intestine are concerned. Percussion elicited no apparent tenderness. The infant was slightly restless, with a rectal temperature of 97.8 F, pulse 130, respiration 40. There was no abdominal distention, but there was rather frequent vomit-

Fig 2—Appearance at the age of 3 months. Lateral view of ventral hernia. The small puncture marks on the lateral surface of the right thigh are due to poorly given hypodermic injections of physiologic solution of sodium chloride during its present illness. The orange in the foreground was about the exact size of the liver at operation but appears larger because of distortion.

ing, and after several hours of observation, at 8:30 p. m., surgical intervention was decided on.

At 9 o'clock, twenty-one hours after birth, the infant was operated on under very light ether anesthesia. There was no preoperative medication. A longitudinal incision was made with the scalpel beginning about 3 cm from the base of the cord on the antero-inferior surface and extended up toward the ligation. An attempt was made to free the cord, but it was found to be firmly adherent with fibrous adhesions to the enclosed mass, and blunt dissection with gauze, scissors and scalpel handle was necessary. Soon after blunt dissection began, sufficient surface of the mass became visible and it was seen to be the liver. After some difficulty, during which the liver surface was very slightly injured with slight bleeding, the entire cord was freed and the mass proved to be the entire liver resting on its postero-inferior border with slight torsion counter-clockwise, with the antero-inferior border elevated about 3 cm above the outer abdominal surface.

The position of the liver was a balance between a pull of the prolonged imperfect ligament, extending from the dome and posterior surface of the liver to the diaphragm, and of a short powerful falciform ligament and round ligaments extending from their usual positions on the anterior and inferior surfaces of the liver to the sheath of the right rectus muscle. The liver was normal as to size, shape and color for a newborn infant. Its surfaces, except the inferior, were covered with dense fibrous adhesions not newly formed. The cord was cut circularly at its base, close to its origin, and removed. The elevation of the antero-inferior border of the liver then

Fig 3—Appearance at the age of 3 months. Crying causing protrusion of the ventral hernia. The orange is again out of focus but except for being a trifle large its general shape well represents the pre-operative hernial mass.

revealed the normal gallbladder in its usual position with its distal tip just extending to the umbilical opening, approximately 3.5 cm in diameter, in the abdominal wall. The cystic, hepatic and common ducts were in their normal positions and relations, with, however, the tension of the common duct pulling the structures of the anterior border of the foramen of Winslow up toward the inferior surface of the liver, to such an extent that they were at the level of the umbilical opening.

<sup>2</sup> Bardeen C R. Personal communication to W A Niebuhr.

As already indicated, the liver rested on its postero-inferior border on the outer surface of the abdomen its dome pointing out perpendicularly from the outer abdominal surface. Instead of its long axis being parallel with the transverse axis of the abdomen, the ligamental torsion caused it to rest at about a 30 degree counter-clockwise angle from that parallel, and also slightly tilted toward the patient's right shoulder, so that its antero-inferior border was elevated about 3 cm from the outer anterior abdominal surface. The liver itself, of course was larger than the umbilical opening, so that incisions were necessary to replace it in the abdominal cavity.

It was evident that during development the abdominal wall had closed relatively early behind the liver and the pull of the ligaments mentioned was modified by the relative narrowness of the umbilical opening through which they were transmitted. Consequently an attempt was made to prolong a first incision extending from the umbilical opening upward toward the sternum, which was done, but it at once became apparent that the diaphragm would soon be entered, so that a long midline incision was made extending from the umbilical opening down toward the pubic region. In so doing, some damage was necessarily done to the falciform ligament, which was only slightly weakened thereby. The latter incision enabled the liver to be placed in the abdominal cavity with considerable

length. It normally returns to the abdominal cavity in a fetus of 40 mm length. If an umbilical hernia were merely the persistence of a normal embryonic or fetal condition the contents would consist of the elements entering into the umbilical loop. Apparently, however, this loop may return to the abdominal cavity, the opening from the abdominal cavity into the umbilical sac may fail to close, and there may be a secondary hernia into the umbilical sac consisting not only of parts of the original umbilical loop but of other structures. In your case the secondary hernia consisted of the liver. The figure enclosed shows how the liver lies relative to the opening into the umbilical sac preceding the return of the umbilical loop into the abdominal cavity. After the return of this loop the liver might be thought of as well situated to slip into the umbilical sac to replace the intestinal loop. The liver is, however, well held in place by ligaments developed from the ventral mesentery of the gastroduodenal loop and by the umbilical vein. It is, therefore, not common for it to enter the umbilical sac. In your case it did so. The time must have been between the latter part of the third month of development and birth. The adhesion between the liver and the walls of the umbilical sac indicates that the hernia took place some time before birth, just how long is open to question. Since the liver appeared to fit fairly well into the abdominal cavity on its return at operation, one might judge that the hernia did not take place until the latter part of fetal life. It is not unlikely that the hernia was a gradual affair and involved a slow stretching of the ligaments of the liver.

We are indebted to Drs. A. H. Parmelee, T. A. Olney and C. R. Bardeen for their valuable suggestions and information.

### THERAPEUTIC VALUE AND EFFECTS OF AMNIOTIN IN GONORRHEAL VAGINITIS IN CHILDREN

JOHN HUBERMAN, MD

NEWARK, N. J.

AND

HOWARD H. ISRAELOFF, MD

IRVINGTON, N. J.

Fig. 4—Median section of a 24 mm embryo from a drawing taken from Kollmann.<sup>3</sup>

difficulty, as that cavity was not accustomed to the increased contents. No attempt was made to anchor the liver in any way. The incision was closed with through-and-through silk-worm tension sutures only, and a cigaret drain was inserted. After closure there was great pressure against the incision from within, due to the increased contents. The infant was returned to its ward at 9:45.

Careful postoperative care, including the frequent and regular administration of 5 per cent dextrose in physiologic solution of sodium chloride hypodermically in the outer surface of both thighs, kept the infant in good condition. There was some vomiting of bile-stained fluid in the first twenty-four hours, but the convalescence was otherwise uneventful.

An examination at the age of 3 months indicated that the liver was apparently in its normal position, except that it seemed to have rotated posteriorly, the liver dulness beginning 5 cm. to the right of the midsternal line.

Bardeen<sup>2</sup> says

#### COMMENT

In the drawing reproduced from Kollmann<sup>3</sup> the umbilical loop may be seen in the umbilical cord in a fetus of 25 mm.

<sup>3</sup> Kollmann, J. C. E. Handatlas der Entwicklungsgeschichte des Menschen. 2. figure 387 after figure 45 of Mall. F. P. Development of the Human Coelom. J. Morphol. 12: 446, 1897.

The serious problem of gonorrheal vaginitis in children has been brought nearer to solution by the ingenious application of a safe and efficient method of treatment demonstrated by Robert M. Lewis. We are of the opinion that this new radical treatment may convert what was formerly a serious social and economic problem into a mild and controlled medical syndrome.

Edgar Allen in 1928 clearly demonstrated that after the injection of 1,005 rat units of ovarian hormone into immature female monkeys, over a period of twenty-one days, there was a definite increase in the number of epithelial layers of the vagina to thirty, as compared to from four to eight layers in the control animal. Associated with these changes, the vaginal smears showed an increased number of partly or completely cornified epithelial cells. Allen further showed that involution of the vaginal structures occurred several weeks subsequent to the cessation of the treatment.

The following facts should be borne in mind. In the adult, the thick cornified epithelium of the vagina is resistant to the gonococci and, therefore, gonorrheal vaginitis, per se, is uncommon. In children, however, the gonococci flourish on the thin delicate mucous membrane and eventually penetrate into the subepithelial spaces. In this manner the disease becomes resistant to local treatment.

Lewis reasoned that if he could by means of the estrogenic preparation theelin change the vaginal epithelium in the immature human to that of the adult type, the gonococcal infection would be eliminated. He carried out this form of treatment on eight children who were selected as showing typical cases of gonorrheal vaginitis. The patients received daily hypodermic injections of 50 rat units of theelin. The total

this form of treatment on ambulatory patients. Six children were selected at random, each one showing a vaginal infection, accompanied by purulent discharge, burning and itching. Vaginal smears and cultures were taken in each case. We were able to demonstrate gram-negative intracellular diplococci, morphologically resembling gonococci, in every smear, and a positive vaginal culture was obtained in one case. Three children of this series gave a history of recent infection, and in three it was of long standing. Two of these children had received local treatment for several months with no results, while four presented untreated infections.

In this investigation, no other form of treatment was employed while amniotin was being given. One hundred rat units of hypodermic amniotin was administered three times a week on five patients of the series, while one child, aged 3½ years, received daily from 120 to 200 rat units of oral amniotin. At no time were there any local or constitutional reactions manifested as a result of the treatment.

It was noted that in the three chronic cases the vaginal discharge disappeared after four weeks of treatment. The children of this group were clinically cured after receiving a total average of twenty-one injections or 2,100 rat units of amniotin. Vaginal smears taken weekly showed a progressive diminution in the number of intracellular diplococci and the appearance of an increasing number of cornified epithelium cells. The vaginal smears were negative for gonococci at the end of four weeks.

The second group, consisting of the three acute cases, required longer and more intensive treatment. The vaginal discharge disappeared after eight weeks of treatment. The children of this group received a total average of twenty-seven injections equivalent to 2,700 rat units. At the end of this period, vaginal smears were negative for gonococci. The child in this group who received oral amniotin required larger daily doses. However, the clinical results were similar to

Fig 1—Vaginal smear before treatment with amniotin showing presence of gonococci and leukocytic elements

amount of estrogenic preparation administered in each case varied. The average total quantity administered was 2,100 rat units. The average duration of the treatment was twenty-one days. The longest course of treatment continued for ninety-eight days. He demon-

#### Treatment in Six Cases

Case	Duration of Infection Before Treatment	Medication	Total Weeks Treated	Total Rat Units	Results
1	1 year	Hypodermic amniotin	7	2,100	Clinically cured followed for 2 months with no recurrence
2	3 mos	Hypodermic amniotin	8	2,400	Clinically cured followed for 2 months with no recurrence
3	3 mos	Hypodermic amniotin	6	1,800	Clinically cured followed for 6 weeks with no recurrence
4	1 week	Hypodermic amniotin	9	2,700	No discharge clinically cured followed for 5 weeks with no recurrence
5	2 wks	Hypodermic amniotin	9	2,700	All symptoms gone negative for gonococci followed for 5 weeks with no recurrence
6	3 wks	Oral amniotin	8	6,000	Clinically cured followed for 3 weeks with no recurrence

strated by means of biopsy the remarkable changes that were effected by the estrogenic preparation. The results were exactly similar to those which Allen had obtained in the immature monkey. In his opinion theelin, by inducing a proliferation of the vaginal epithelium, rapidly clears up the discharge and appears to eradicate the gonococci.

Realizing the importance of this work, we decided to investigate further this plan of treatment in juvenile gonorrheal vaginitis, using another estrogenic preparation, amniotin<sup>1</sup>. Appreciating the difficulty of isolating and hospitalizing every case of vaginitis, we applied

Fig 2—Vaginal smear seven weeks after treatment with amniotin was begun showing complete absence of gonococci and leukocytes and the presence of cornified epithelial cells

those of the other cases. Regardless of the amount of amniotin administered, we did not observe any hypertrophy of breasts or labia, or any uterine bleeding.

Throughout this study, biopsies from the lateral wall of the vagina were made in each case before and after amniotin injections. The microscopic examination of the sections removed before treatment showed the thin delicate epithelial layers of the child's vagina, with

<sup>1</sup> The amniotin used in this study was supplied by E. R. Squibb & Sons.

marked round cell infiltration, significant of inflammatory changes. There was an absence of a definite cornified layer of epithelial cells.

The examination of the biopsy sections after treatment revealed striking changes in each case. There was a definite increase in the number of epithelial layers, and the inflammatory changes were no longer present. The most significant change, however, was the presence of a definite layer of cornified epithelial cells.

We observed a direct relationship between the clinical results and the histologic picture. In those cases in which the discharge persisted there was an absence of a layer of cornified epithelial cells, whereas in the cases considered clinically cured the layer of cornified cells was present.

As a result of these observations we are of the opinion that the success of this mode of treatment depends mainly on the development of a layer of cornified epithelial cells. This layer of cells is analogous to the desquamating type of cells found in the normal adult vagina. The acquired layer of cornified epithelial cells acts as a protective barrier against the rapidly multiplying gonococci and thus prevents reinfections. On the other hand, the gonococci that have previously

Fig. 3—Vaginal epithelium (biopsy) before the administration of amniotin, showing thin epithelial layer and inflammatory changes.

penetrated into the subepithelial spaces are destroyed by the normal phagocytic action of the leukocytic elements.

A question may arise at this time regarding the safety of this mode of treatment when administered to a child.

Hartman, as a result of his experiments on animals, is of the opinion that the dosage of estrogenic preparation required to produce the vaginal reaction is far less than that which would lead to injurious changes or uterine bleeding. He considers, furthermore, that estrogenic substance is so readily excreted by the kidneys that no deleterious effect can result from cumulative action. Lewis further showed that in his series of eight children treated with an estrogenic preparation there was an absence of any deleterious effects and that involution of the vaginal structures occurred after cessation of treatment. In our series we also noted definite involuntary changes occurring five weeks after cessation of treatment.

In order to investigate further the effects of amniotin on the anterior pituitary gland and ovaries, we attempted to determine the amount of estrogenic substance and anterior pituitary-like principle excreted in

a twenty-four hour urine specimen during and after treatment. The results obtained thus far lead us to make the following preliminary conclusions:

1 Amniotin has no cumulative action, as is evidenced by a constant presence of this product in the urine of the children receiving treatment.

Fig. 4—Vaginal epithelium seven weeks after treatment with amniotin showing increased number of epithelial layers and presence of a layer of cornified epithelial cells?

2 The renal threshold of amniotin varies in different individuals.

3 The amount of estrogenic substance in the urine as determined by the Kurzrok method is directly proportional to the intensity of the treatment.

Additional data at present as to the effect of administration of an estrogenic preparation on the anterior pituitary gland is not possible, owing to the fact that our experimental studies have not been completed.

#### SUMMARY

The following facts should be emphasized:

1 Although there is produced an increase in the number of epithelial layers of the vaginal mucous membrane after treatment by the estrogenic prepara-

Fig. 5—Vaginal epithelium four weeks after termination of amniotin administration showing partial involutionary changes and a definite layer of cornified epithelial cells.

tion, this is not the sole factor responsible for the eradication of the disease.

2 The most important aid in combating gonorrheal vaginitis is the formation of the cornified layer of epithelial cells, which acts as a barrier against reinfection.

3 The method of treatment described is safe, as has been shown by the work of Hartman and Lewis, and by our own laboratory and clinical results

4 There is a definite involution of the vaginal structures after cessation of treatment

5 This mode of treatment does not necessitate the hospitalization of the patient

6 In view of our encouraging results with oral ammotin we believe that this preparation offers a simple method of treatment which may eradicate the disease

## Clinical Notes, Suggestions and New Instruments

### A SIMPLE SIGMOIDOSCOPIC ASPIRATOR

WILLIAM Z FRADKIN, M.D., BROOKLYN  
Assistant Surgeon, Jewish Hospital of Brooklyn

The recent outbreaks of amebiasis have made many physicians 'ameba conscious'. This added interest has afforded an opportunity to evaluate methods of collecting specimens from the diseased colon. It soon became apparent that a stool specimen sent to the laboratory is not the most desirable material for examination. It is rarely fresh. It is cold. The preparation of a suspension is not a pleasant task and often is very revolting to the technician or physician. Specimens obtained through the sigmoidoscope not only obviated these disadvantages but resulted in many more positive examinations. Paulson and Andrews<sup>1</sup> have had similar experiences

Above the parts of the sigmoidoscopic aspirator below the instrument assembled and ready for passage through the sigmoidoscope

Recently I described a sigmoid aspirator<sup>2</sup> for procuring fresh sigmoidal contents. That instrument is particularly valuable in cases of diarrhea, in the preulcerative stages of colitis or in debilitated cases in which a sigmoidoscopic examination is objectionable. However, when ulcerations are seen through the sigmoidoscope, direct aspiration of the exudate from and about the ulcers is the procedure of choice. For this purpose a sigmoidoscopic aspirator<sup>3</sup> was devised. By means of this simple instrument, extremely gratifying results were obtained in rapidly detecting amebas lodged in the depths of ulcerations. The sigmoidoscopic aspirator consists of a long narrow tube 19 inches long and one-eighth inch in diameter, bent at an obtuse angle 4 inches from the proximal end. The distal end is bulbous and smooth while the proximal end fits the tip of a luer syringe. A spiral spring is mounted over the piston of a 2 cc syringe in order to facilitate aspiration with one hand while the other hand steadies the sigmoidoscope.

#### SUMMARY

The simple aspirator here described obtains exudate direct from ulcerative lesions in the sigmoid through the sigmoido-

### TUMOR OF THE CAROTID BODY

A. CLIFFORD ABBOTT, M.D., C.M., F.R.C.S. (En.), AND  
EARL STEPHENSON, M.D., CH.M., WINNIPEG, MANITOBA

Tumors of the carotid body are so rare that few surgeons see more than one in a lifetime. In 1929, Bevan and McCarthy<sup>1</sup> collected and tabulated 134 reported cases. From their series it is strikingly apparent that operative removal of these

Fig. 1—Tumor of the carotid body surrounding the external carotid artery. The hypoglossus nerve is seen running across the outer surface of the tumor.

Fig. 2—Section of a tumor of the carotid body slightly reduced from a photomicrograph with a magnification of 150 diameters.

growths is associated with a very high mortality (33 per cent) and a long list of complications (30 per cent).

The following case was attended by one of us.

A woman, aged 53, sought medical advice in April, 1931, because of dyspnea, tachycardia, nervousness, irritability and

<sup>1</sup> Bevan, A. D. and McCarthy, E. R. Surg. Gynec. & Obst. 49: 764-779 (Dec.), 1929.

dizzy spells. There had also been some dysphagia. For nine years she had noticed a small nodule below the angle of the left mandible, and for the last five years the thyroid had been increasing in size. The small nodule at the angle of the mandible had enlarged gradually and at times became very painful. This pain radiated to the left postauricular region.

The patient had had no severe illnesses but had had frequent sore throats and an occasional rheumatic pain. She was the mother of eight children. The menopause began at 48 and was now completed.

angle of the left mandible there was a firm smooth swelling which the patient said increased in size during wet weather. This solitary nodule was quite discrete and tender to pressure, moved at right angles to the carotid sheath but not up and down, and did not pulsate. Our preoperative diagnosis in this case lay between an accessory thyroid or a tumor of the carotid body associated with an adenomatous goiter.

A bilateral resection of the thyroid was done, April 13. The large right lobe extended behind the trachea. It was deemed unwise to remove the nodule from below the mandible at this

The patient was stout, weighing 181 pounds (82 Kg). The general physical examination was negative except for a blood pressure of 190 systolic and 110 diastolic, septal tonsils, and the two masses in her neck. There was an adenomatous enlargement of the right lobe of the thyroid extending from the ear to the thorax. The left lobe was smaller. Just below the

operation. The patient had a most uneventful convalescence. April 18 under ethylene and oxygen anesthesia the tumor was exposed by an oblique incision below the angle of the left mandible. There was considerable hemorrhage. The tumor, firm, the size of a walnut and densely adherent to the underlying structures, was loosened at its lower extremity (fig 1).

The external carotid artery, which was involved in the growth, was ligated under vision. The upper limit of the growth was defined and the mass removed with great difficulty and considerable hemorrhage. Some enlarged lymph glands in this region were removed. The wound was sutured with no drainage. The anesthetist noted that there was an unusual amount of respiratory embarrassment for some unknown reason.

The patient complained of severe pruns seeming to start in the left side of the neck and radiating to the forehead on the same side. On the second day she complained of blindness

Dr William Boyd examined the tissue and reported that the tumor consisted of large cells with pale, rather clear, cytoplasm and round or oval nuclei of normal vesicular appearance. The cells showed a distinct alveolar grouping, the groups being separated by delicate strands of connective tissue. There were in addition occasional dense fibrous septums, which passed into the tumor from the capsule. Scattered through the section there were a few dense collections of cells with small dark hyperchromatic nuclei and very scanty cytoplasm. These resembled lymphocytes (fig 2).

in the left eye and blurred vision in the right for about ten minutes. On the third day there was some swelling and tension in the wound. This aggravated the pain in her head. There was no infection. The sutures were removed the fifth day and she left the hospital the seventh day after operation. The swelling in the wound disappeared in about two weeks.

Sept 12 1931 the patient was much better. She had, however a definite speech impediment, which she described as a "lisp." Her tongue was smaller than normal, sore on the left side and deviated to the left when she protruded it. Occasionally this side of her tongue became swollen. There was a burning sensation below the left ear. Her general condition,

however, was much improved. Her blood pressure had remained about the same, 180 systolic and 110 diastolic.

April 17, 1932, the patient reported by letter that she still complained of a stiffness and at times a throbbing in the scar. Her speech was much improved but the impediment increased when she was tired. Her tongue still deviated to the left when protruded but was less "thick" than formerly.

June 19, 1933, the patient reported in response to a follow-up letter. She still had pruritus in her head, especially if she was startled. Speech was definitely improved.

#### COMMENT

In our opinion, most of the patient's head symptoms were due to high blood pressure. The defective speech was undoubtedly due to accidental section of the hypoglossal nerve.

#### COLD ALLERGY

LEE W. PAUL, M.D., LOS ANGELES

A recent editorial in THE JOURNAL<sup>1</sup> presented recorded occurrences of cold allergy, discussed the symptoms and causes, and particularly emphasized the fact that such a reaction should be considered as a possible cause of death during bathing in a cold body of water. Just before the appearance of the editorial, a patient described to me a cutaneous reaction of this type.

#### REPORT OF CASE

D. W., a white man, aged 29, married, a grocery clerk, called my attention to a skin condition which he described as a "bumpy affair" that occurred when he immersed his hands or body in cold water even for only a short time. He stated that he had ceased ocean bathing and plunge swimming because the condition occurred on all exposed areas. Driving against cold rain or mist would also produce it on the exposed areas. Furthermore, swallowing ice water or eating frozen desserts would cause his "throat to close up." At the time of this

Fig. 1—Area of forearm just previous to experiment

conversation which took place in his store I told him that such reactions as his had been reported in medical literature.

In the course of a few days the editorial mentioned came to my notice. At my request the man came to my office and the editorial was read to him. He said, "that fits my case exactly, and I will demonstrate for you just what happens when ordinary cold tap water is allowed to run over my hand and forearm." He allowed tap water at a temperature of 64 F to run over his hand and forearm for three or four minutes at the end of which time one or two wheals appeared. Within a minute or two there were several more, and at the end of ten

minutes there were so many that they coalesced and formed a semiedematous mass. The illustrations show the normal appearance before the experiment and the beginning of the reaction phase characterized by discrete wheals, before confluence took place.

The patient stated that the condition caused a little itching but mainly a sense of tenseness. Warmth hastened its disappearance but without the use of warmth the reaction lasted about thirty minutes. In this case there had never been a

Fig. 2—Same area as in figure 1 showing wheals forming and coalescence farther down on the arm

general systemic reaction, as reported by Horton and Brown.<sup>2</sup> There was, however, evidence around the wrists of such a continuous outcrop of wheals that the itching had caused sufficient scratching of these areas to cause denuding of the tops of wheals.

#### COMMENT

An inquiry into the history shows that a condition of hyper sensitivity has existed for approximately four years. No opinion had been given him in his heretofore casual conversations with physicians. It is interesting to record that he was very sensitive about his condition, not wanting to let his friends know of it, when he came to see me he even told his employer that he was desirous of seeing me "because he was nervous."

I hope that the understanding he now has that the condition is not a "blood disease" will make him less sensitive regarding it. Treatment by daily immersion of the hands in colder and colder water, as was used in the reported cases of Horton and Brown, has been advised.

#### SUMMARY

A case of cold allergy in which some reactions were observed and other reactions were described by the patient further strengthens the theory that such reactions under circumstances of bathing in large bodies of cold water may be a cause of disagreeable or serious symptoms, or even death.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.  
CHICAGO

*NOTE*—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by the various members are incorporated in the final draft prepared for publication. The series of articles will be continued from time to time in these columns.—ED

#### THERAPY OF CONJUNCTIVITIS

OUTLINE BY SANFORD R. GIFFORD, M.D.

Although bacterial invasion is the exciting cause of most of the conjunctival inflammations, particularly the more severe and the more acute forms, the application of antiseptic solutions or ointments to the tissue surfaces while not without value, is less effective than could be desired, at least so far as destruction of the organisms or inhibition of their growth is concerned. This is due to the well recognized fact that within a relatively short time, frequently before the patient is first seen the bacteria have invaded the tissues to a greater depth than that to which the antiseptics can penetrate. It is only at the moment of contamination while the micro-organisms are still on the surface that disinfection can actually be accomplished (see prophylaxis of gonorrheal conjunctivitis).

The fact also must be kept in mind that conjunctivitis may be caused by chemical irritation, such as exposure to irritant gases, face powders or eyelash dyes, and that in these the use of bactericides, all of which are irritant, would add insult to injury. For instance, a case of conjunctivitis may not yield to treatment until the patient has given up smoking and stays away from smoke-contaminated rooms for days or weeks.

The inflammatory process itself should be regarded as the most important factor to be dealt with, and all measures designed to limit its severity and extent and to hasten its resolution should be adopted, so far as practicable.

Compresses must not be used in any form of conjunctivitis—unless they are accompanied by frequent irrigations (see gonorrheal ophthalmia in the adult)—as they force the lids to close, thus converting the conjunctiva into a closed sac and impeding drainage.

Before the patient goes to sleep, petrolatum should be applied to the edge and lashes of the lower eyelid to keep the lids from becoming stuck together during the night, which also interferes with drainage.

#### CONJUNCTIVITIS DUE TO CHEMICALS

In burns from alkali, irrigation is advisable with much diluted acetic acid. Sodium bicarbonate solution (5 per cent) is best for acid burns.

#### ACUTE CATARRHAL CONJUNCTIVITIS (PINK EYE)

*Prophylaxis*—The period during which the disease is transmissible corresponds, for practical purposes, with that in which discharge is present, so that children may be allowed in school after this disappears. Treatment should, however, be continued for about another week or even longer, and precautions of special cleanliness should be observed for at least this length of time.

*Treatment*—As this disease is often self limited, running its course within six to eight days in mild cases, the object of treatment is simply to shorten this course, to relieve the patient's discomfort and to reduce the period of infectivity. Corneal complications probably develop only when some trauma to the cornea occurs.

*Cleansing*—Before a drug designed to kill bacteria or to inhibit their growth is used, any purulent or mucoid secretion should first be removed from the conjunctival sac by lavage with physiologic solution of sodium chloride, as precipitation of the drugs on contact with such secretion greatly reduces and may completely nullify their effect.

*Antiseptics*—A smear should be made when a case is first seen, and if the pneumococcus is present (the most common cause in North America) the use of a freshly prepared 1 per cent ethylhydrocupreine hydrochloride (optochin) solution twice a day may materially shorten the course of the disease. As instillations of this drug are painful in certain persons, a weak solution of a local anesthetic, 0.5 per cent butyn or 0.25 per cent panto-caine, may be prescribed for use before the ethylhydrocupreine. In cases not due to the pneumococcus other antiseptics, such as metaphen 1:2,500, mercuric oxy-cyanide 1:5,000 or acriflavine hydrochloride 1:1,500 are preferable, and these have proved clinically of almost equal value in pneumococcal conjunctivitis. They may be used four times a day, as they are not painful or irritating in these concentrations. Mild silver protein (argvrol) or neosilvol which are often employed in 10 to 20 per cent solutions have little if any bactericidal effect but seem to produce symptomatic improvement. Prolonged use is prohibited by danger of local argyria.

In severe cases, indeed in any case, the duration of symptoms may be shortened by one or more direct applications of 2 per cent silver nitrate. These should be made by the physician and must be preceded by instillation of 2 per cent butyn or 0.5 per cent panto-caine. After about ten minutes the drug may be painlessly applied to the everted lids, left thirty seconds and washed off with physiologic solution of sodium chloride. A 2 per cent zinc chloride solution employed in the same way is also effective in certain cases. Applications of moist or dry heat after each instillation lessen the discomfort and probably aid in hastening recovery.

#### GNORRHEAL CONJUNCTIVITIS (OPHTHALMIA NEONATORUM)

*Prophylaxis*—State laws (Illinois, 1933) make compulsory the use of 1 per cent silver nitrate solution at birth or such other antiseptic agents as the board of health may recognize. It has not however, recognized any other agents and the substitution of any other, especially of the mild silver proteins, for the 1 per cent silver nitrate is therefore illegal, besides being, as regards the latter drugs, perfectly useless for prophylaxis. The silver solution, to be effective, must be instilled immediately after birth and this duty should be performed by the obstetrician himself or by an experienced assistant under his direct supervision.

*Treatment*—When conjunctival discharge appears in an infant after birth, smears must be made at once and stained carefully by Gram's method. If no gonococci or other organisms are found in the secretion, a spread of the superficial epithelial cells obtained with a sharp spatula may reveal organisms before these are present.

in the secretion. If no organisms are found, conjunctival inflammation in the new-born should be treated with irrigations frequently enough to keep the sac free from secretion, and smears should be repeated if the symptoms persist more than one or two days, the duration of the occasional inflammation produced by silver nitrate.

Once the diagnosis of gonorrheal ophthalmia is made, the child must be isolated and given day and night nursing. In infants both eyes are usually involved, but in a few cases one is left intact, and such eyes should be protected with a Buller's shield or other water tight dressing (e. g., a cleansed noninflammable x-ray film applied by a frame of adhesive plaster), which is changed every day so that the eye may be examined for beginning inflammation.

**Cleansing.** In this condition one's best efforts must be directed to the prevention of corneal complications. Irrigations of the conjunctival sacs to keep the cornea free from contact with secretion are therefore the most important form of treatment. Physiologic solution of sodium chloride and 1:15,000 potassium permanganate are the best irrigating solutions and must be used frequently enough so that no secretion is allowed to collect in the sac. This may mean every half hour night and day for several days in severe cases. In others, every hour or every two hours is sufficient. The lids should be freely manipulated during irrigation so that any secretion clinging to the cornea or conjunctiva is dislodged, and enough fluid should be used to remove all such secretion from the sac. The lid borders should be kept anointed with petrolatum so that they may not stick together between irrigations. It is the physician's duty personally to instruct nurses in the technic of irrigation.

Antiseptics may also be of value, though the majority of cases will clear up on irrigations and proteotherapy alone. Acriflavine hydrochloride 1:1,500 or metaphen 1:2,500 instilled three times a day after irrigations may be useful. It is doubtful whether mild silver protein, so commonly applied, serves any purpose. Silver nitrate was formerly much employed but is not without danger to the cornea and is seldom necessary when irrigations are properly performed. In some cases, with discharge persisting after the swelling has subsided, a few careful applications of 2 per cent silver nitrate on the everted lids and retrotarsal folds, the cornea being carefully protected, will aid materially. It should be neutralized with physiologic solution of sodium chloride while the lids are held everted. Copper sulphate crystals may also be used in such cases and may even prove of more value than the silver nitrate.

**Proteotherapy.**—The use of foreign protein injections undoubtedly shortens the course and prevents corneal complications in many cases. Milk boiled for four minutes serves admirably for this purpose. The initial dose is 1 cc., and this is increased to 1.5 and 2 cc. on succeeding injections, which are best repeated every third day for from three to five doses. Diphtheria antiserum has also been found valuable for this purpose.

**Corneal Involvement.**—When the cornea is involved, irrigations are continued, the pupil is kept dilated with 0.5 per cent atropine sulphate solution, and more vigorous efforts are made to clear up the discharge with antiseptics and foreign protein injections. Silver nitrate is indicated here, provided there is no ulceration, and one takes care to protect the cornea against direct

action by the chemical. The application may be repeated daily or every two days. If a localized corneal ulcer is present, direct application of trichloroacetic acid possibly once every other day may be made. When, as usual, a large area of cornea is denuded, it is best to cover the whole cornea with a conjunctival flap. If possible, this should remain in place until the secretion has cleared up under the treatment described.

**Gonorrheal Ophthalmia in the Adult.**—The treatment in most details is as already described. On account of much greater danger of corneal complications, the most vigorous means are employed from the outset. Most important is protection of the other eye by Buller's shield or by a cone made of transparent noninflammable x-ray film. For proteotherapy in adults, intravenous injection of from 40 to 80 million organisms of a standard typhoid vaccine is the most dependable means of securing a good febrile reaction. This should be repeated every third day (i. e., at intervals of two fever-free days) and the dose increased according to the reaction. For such small doses the commercial vaccine must be diluted accurately with sterile physiologic solution of sodium chloride in a "tuberculin" syringe.

**Local Treatment.** Iced compresses used during the first two or three days are of value when much swelling of the lids is present. After this time heat from an infra-red lamp may be employed. The indications for silver nitrate are the same as in ophthalmia neonatorum, but many will prefer to use it from the beginning in any case presenting profuse secretion. A careful watch must be kept for early involvement of the other eye, the shield being changed daily or every two days for that purpose.

#### CHRONIC CATARRHAL CONJUNCTIVITIS

The commonest cause of chronic catarrhal conjunctivitis is the diplobacillus of Morax-Axenfeld. Since the treatment of such an infection with zinc is exceedingly satisfactory, it is of great value to make an exact diagnosis by examination of smears or scrapings from the inner or outer angle. A Gram stain will usually reveal numerous characteristic large gram-negative bacilli in pairs or chains of pairs.

**Antiseptic Treatment.**—The instillation by the patient of from 0.25 to 0.4 per cent zinc sulphate solution three or four times a day will cure many mild cases if continued for six or eight weeks. Many chronic cases, however, require applications by the physician of stronger zinc solutions twice a week, and cure in all is hastened by such applications. Previous instillations of 1 per cent butyn or 0.5 per cent pantocaine are necessary, after which 2 per cent zinc chloride is dropped freely on the everted lids, worked into the folds by manipulating the lids, and washed off after thirty seconds with 0.2 per cent zinc chloride. From three to four weeks of such applications are sufficient for most cases, the weaker zinc solution being used by the patient in the meantime, and for one month after all symptoms are relieved. When, as is often the case, the skin at the outer angle is cracked and excoriated, these areas should be covered with ointment of zinc oxide at night.

Chronic conjunctivitis may also be due to the pneumococcus, and this form often is exceedingly resistant to treatment. A 1 per cent solution of ethylhydrocupreine hydrochloride instilled three times a day is of definite value here, perhaps of more value than any

other drug. Acriflavine hydrochloride may be employed with good results in most cases if treatment is continued long enough. Applications of 2 per cent silver nitrate by the physician will hasten a cure in most cases. They should be preceded by a drop of local anesthetic and followed by irrigation with physiologic solution of sodium chloride.

**Medication of Lacrimal Sac.** Before the use of medication in acute or chronic conjunctivitis it is often advisable to shrink the membranes in the canaliculi leading to the lacrimal sac by the use of epinephrine solution 1:1,000. This results in the medication more readily finding its way from the conjunctival sac into the lacrimal sac, so that it acts to better advantage than if it must work its way through less patent openings because of swollen epithelium.

**Other Causal Treatment.**—In any case of chronic conjunctivitis, search for other factors, such as eye strain, blepharitis, inflammation of the meibomian glands and exposure to chemical agents or those likely to produce allergic reactions, must not be neglected, as they are a common cause of long standing conjunctival inflammation.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE H. A. CARTER, Secretary

### WHAT CAN THE GENERAL PRACTITIONER EXPECT FROM INFRA-RED THERAPY?

The generators of infra-red or thermal radiation usually consist of a concave reflector at the focus of which is the heating element. This element may be composed of an incandescent lamp or a heater consisting of a solid rod or a resistance wire embedded in or wound round an electrically nonconducting refractory material such as "steatite," lava or porcelain. The color of the surface, whether white or black, is unimportant.

The incandescent filament radiators that are enclosed in glass bulbs emit radiation of wavelengths 4,000 to 40,000 angstroms<sup>1</sup> with the maximum emission at from 11,000 to 20,000 angstroms, depending on the temperature of the filament. Only a small amount of radiation is emitted by the glass of the bulb.

The radiant heaters that are not enclosed in glass emit perceptible radiation of all wavelengths throughout the infra-red to 150,000 angstroms, beyond which point the intensity is very low. Carbon dioxide and water vapor, which are present in the air, selectively absorb certain wavelengths in the infra-red. With increase in temperature the maximum emission shifts toward the short wavelengths, so that for a surface temperature of from 300 to 400 C (from 570 to 750 F) the maximum emission is not well defined, extending from 40,000 to 50,000 angstroms, whereas at a low red heat (from 600 to 800 C) the maximum emission becomes more sharply defined and lies between 20,000 and 30,000 angstroms. Moreover, the infra-red radiation from the latter is far more intense (from eight to ten times greater) than that emitted by the heater at 300 C. The reflectors surrounding these heaters are quite nonselective and hence they

have no appreciable effect in modifying the spectral composition of the radiation emanating from the heater.

These generators are usually for local application of infra-red or thermal energy and when used in treatment may be held in the hand or mounted on stands directing the radiant energy toward the diseased part. Satisfactory apparatus may be procured from dealers at a nominal sum.

From the sources here considered (electric bulbs and resistance coils), the penetration of heat into the tissues is never great under therapeutic conditions. Sonne<sup>2</sup> noted that during the applications of incandescent radiation of maximum tolerance the surface temperature of the skin rose to 43.8 C (110.8 F), while the subdermal temperature at a depth of 0.5 cm was 47.7 C (117.8 F). On application of infra-red radiation he observed temperature differences of 45.5 C (113.9 F) on the skin surface and 41.7 C (107 F) at the depth of 0.5 cm.

Loewy and Dorno<sup>3</sup> reported skin surface temperatures of from 41 to 44 C (105.8 to 111.2 F) during irradiation with long infra-red rays, while the temperature at a depth of from 10 to 25 mm was about 38 C (100.4 F). They found that the short infra-red and visible rays of sunlight caused a temperature of 38 C (100.4 F) on the skin surface and 40 C (104 F) at a distance of 25 mm beneath the surface.

Studies of Baehem and Reed<sup>4</sup> show that a considerable percentage of the radiation in the visible and near infra-red regions of the spectrum penetrate through the skin and into the subcutaneous areas, while radiation of the far infra-red spectrum has practically no penetration. Most of the near infra-red radiation was absorbed in the upper layers of the skin, while most of the visible radiation was absorbed in the lower layers.

Following local exposure there is directed to the part increased circulation of blood, which tends to keep the temperature of the tissues constant. The blood itself is also warmed but the heat regulating mechanism of the body operates to maintain the blood nearly constant in health and it is therefore difficult or impossible to "heat up" deep lying structures by increasing the degree of heat or prolonging application. However, superficial structures, such as skin, tendons and fibrous tissue, are actually heated to a limited degree and may be injured by careless application.

#### THERAPEUTIC INDICATIONS

The therapeutic indications for the use of external heat can be grouped under the two general headings of general exposure and local exposure, according to whether a systemic or a local effect is desired. Systemic effects confine their application for the most part in medical as contrasted with surgical conditions and are valuable chiefly in the treatment of acute and chronic arthritis or rheumatoid conditions.

In this article, only the use of local radiant heat will be considered. The therapeutic indications for the use of heat locally are chiefly in the following fields: surgery, following fractures, dislocations, sprains, cicatrices after operating procedures, arthritis when a limited influence on the joints is desired, myositis, neuritis, and circulatory disturbances of the extremities.

<sup>2</sup> Sonne C. *Acta med Scandinav* 54: 336, 1921.

<sup>3</sup> Loewy A. and Dorno C. *Strahlentherapie* 20: 411, 1925.

<sup>4</sup> Baehem A. and Reed C. I. *Am J Physiol* 97: 86 (April) 1931. *Arch Phys Therapy* 12: 581 (Oct) 1931.

<sup>1</sup> An angstrom is one ten millionth millimeter or 1/10,000,000 mm.

*Local Application of Heat in Arthritis*—The application of heat locally to a joint or joints in arthritis is often of the highest therapeutic value. The principle holds, here as elsewhere, that reliance must not be placed on this measure alone. It must be considered in conjunction with other principles of treatment of the disease as a whole and of the joint in particular. The measure most often used in arthritis in conjunction with local external heat is massage and although often misused it constitutes an almost necessary adjunct to the use of heat alone, especially in the form of stroking massage.

Application of heat should not be carried to the point of irritation and should depend for its effect on repeated use, for example, once or twice a day over a period varying from ten minutes to half an hour. Local sweating generally occurs and the part should be kept warm after the treatment.

*Neuritis and Neuralgia*—Heat is of the greatest value in inflammations of the peripheral nerves and in vascular diseases in which the nervous system is implicated. In the various neuritides, such as intercostal neuralgia or inflammation of any of the nerves in the limbs, heat, and particularly radiant heat, allays the inflammation. In intercostal neuralgia, care must be taken to give a sufficient amount of treatment, for the penetration here must be deeper than in the limbs. Here heat is only one mode of treatment, as frequently a neuritic condition is part of arthritis.

*Circulatory Disturbances of the Extremities*—In certain vascular diseases of the limbs, such as erythromelalgia, Raynaud's disease, thrombo-angitis obliterans, thrombophlebitis and endarteritis obliterans, radiant heat applied to the diseased parts more or less constantly over a period of days may cause an alleviation of the symptoms. Starr reported that at temperatures under 30 C (86 F) the feet showed varying degrees of cyanosis and the patients complained of pain. Between 33 and 35 C (91.4 and 95 F), pain diminished or disappeared and the color of the feet most closely approached the normal. Above 35 C (95 F), cyanosis reappeared and pain returned.

A temperature of between 30 and 35 C (86 and 95 F) was employed in the treatment of these conditions, maintained round the feet day and night by means of a thermoregulated foot cradle. Under such conditions some patients preferred temperatures differing slightly from that which they chose in the acute experiment, so temperatures between 32 and 37.5 C (89.6 and 99 F) have been used for prolonged treatment.

*Chronic Diseases of the Nervous System*—In hemiplegia or lateral sclerosis, when the limbs are spastic, radiant heat will decrease the spasms and contractures, at least for a time, and will moderate other symptoms.

The application of radiant heat energy as a treatment of surgical conditions is valuable. Local application of heat produces relaxation of the tissues, particularly of the voluntary and involuntary muscle fiber. Spasm of the skeletal muscle is relieved. The walls of the smaller arteries relax and the vessels dilate. By reason of these conditions, a greater amount of arterial blood flows to the part, bringing oxygen and nutriment. Furthermore, the increased blood flow induced on the venous side carries away in a larger degree the products of normal or abnormal metabolism, so that they do not remain as local poisons or irritants but are excreted from the body through natural channels.

Immediately following an injury there is an inflammatory reaction with heightened local metabolism and elevation of temperature. This condition is treated by rest, elevation and application of cooling lotions, but the succeeding subacute and chronic stages of swelling, sluggishness, anemia and lowered metabolism are to be treated by local application of radiant heat, massage and passive and active exercise carried out in a manner to avoid repetition of traumatism of the structure already injured.

In the following conditions the application of radiant heat, accompanied later by massage, may be of value. It must be emphasized that the use of heat in surgical conditions is not to be considered alone but only in connection with general surgical principles and that its benefits are often obtainable only by the coincident use of massage for which it paves the way.

*Fractures*—A simple fracture of the shaft of a long bone not involving a joint or near a joint and not complicated by a marked or persistent swelling at the site of the fracture or of the extremity distal to the fracture may not require this form of treatment. But fractures into or about the joints, such as Colles' fracture or Pott's fracture, accompanied by swelling at the site of the fracture and particularly by swelling of the hand or foot, are best treated by radiant heat followed by massage. This treatment should be begun within a few days after reduction of the fracture.

*Sprains and Dislocations*—Treatment is similar to that of fractures near joints as just described. Splints or casts should be removed and replaced again after daily treatment by heat application and massage. On the whole, fixation of a removable plaster splint and daily radiant heat and massage treatments are to be preferred to strapping with adhesive plaster, which does not permit the use of physical therapy.

*Traumatic Synovitis and Tenosynovitis*—After the first stage of acute inflammation lasting from one day to possibly a week, the secondary stage of absorption of effusion and restoration of function of the joint begins. During this stage, radiant heat and massage are vitally important in aiding these processes.

*Contusions and Muscle Sprains*—Similar means of treatment are valuable also in these conditions to secure absorption of the products of hemorrhage, to eliminate swelling and pain, and to secure restoration of function. Collections of blood, if not absorbed, may form cysts or may be infected through the blood stream and become abscesses. The development of such abscesses after local injury is not uncommon. It is of importance to secure as early absorption of blood clots as possible. Treatment should be continued as long as tenderness in the injured part persists.

*Bursitis*—This condition, often seen about the elbow and shoulder joints, for example, and resulting from acute or chronic strain, is susceptible to improvement or cure by heat and massage.

*Stiff Joints*—Even in fairly severe cases of fibrous ankylosis, some benefit is to be obtained by using radiant heat followed by massage, stretching and exercise, while in the milder cases even complete restoration of function in the joint may be expected. Before performing any operation on or about such a joint the surgeon should employ heat application and massage persistently and faithfully for some weeks or months to secure as much improvement as possible.

In the condition of flatfoot due to traumatism or possibly to infection, semirigid and spastic feet can

frequently be made more flexible by these means of physical therapy in conjunction with the use of proper supports for the feet

Chronic backache can be profitably treated by radiant heat and massage, by proper means of support for the muscles and ligaments that are under strain, and by properly graded exercise to improve posture. Acute attacks of what may be called myositis or lumbago are also advantageously treated by means of radiant heat and massage by support or by complete rest in bed for the time being

## Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING AMENDED GENERAL DECISION  
RAYMOND HERTWIG Secretary

### TOLERANCES FOR ARSENIC, COPPER AND LEAD IN FOODS

(THIS DECISION CONTEMPLATES ONLY ADDED POISONS OR POISONOUS CONTAMINATIONS)

Because of the recognized toxicity of certain metallic substances it is in the interest of public health to protect foods from contamination with such materials. Precautions should be taken in the manufacture, culture, treatment, preparation, processing, packing or preservation of foods that they shall not be contaminated with arsenic, copper or lead compounds or if such contaminations are unavoidable that they be reduced to amounts that are within the limits of safety. To this end equipment and materials used in the manufacture of prepared foods should be carefully guarded and controlled.

Foods to be eligible for acceptance shall not contain arsenic, copper or lead by contamination in excess of the tolerances established by the United States Department of Agriculture:

- (a) 1.06 parts of arsenic (as As) per million of food [1.4 parts of arsenic (as As<sub>2</sub>O<sub>3</sub>) per million of food]
- (b) 30 parts of copper (as Cu) per million of food
- (c) 2 parts of lead (as Pb) per million of food

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.  
RAYMOND HERTWIG Secretary

#### BEECH-NUT PRESSURE COOKED OATMEAL CERE-JEL

(SLIGHTLY SEASONED WITH SALT)

**Manufacturer**—Beech-Nut Packing Company, Canajoharie, N. Y.

**Description**—Sieved cooked oatmeal, seasoned with salt.

**Manufacture**—See Beech-Nut Pressure Cooked Farina Cere-Jel (THE JOURNAL, May 26, 1934, p. 1762) and Beech-Nut Strained Carrots (THE JOURNAL, Nov. 11, 1933, p. 1562).

Analysis (submitted by manufacturer) —		per cent
Moisture		88.2
Total solids		11.8
Ash		0.9
Sodium chloride		0.5
Fat (ether extract)		0.3
Protein (N × 6.25)		2.2
Crude fiber		0.2
Carbohydrates other than crude fiber (by difference)		8.2

**Calories**—0.4 per gram, 11 per ounce

**Claims of Manufacturer**—Especially intended for infants, children and convalescents and for special smooth diets. Only warming is required for serving.

#### DIAMOND CRYSTAL IODIZED SIIAKER SALT

**Manufacturer**—Diamond Crystal Salt Co., Inc., St. Clair, Mich., Division of General Foods Corp., New York.

**Description**—Table salt containing added calcium phosphate (0.8 per cent) for promoting its free-running properties, sodium bicarbonate (0.5 per cent) and potassium iodide (0.023 per cent).

**Manufacture**—Dissolved salt, hydraulically mined from underground deposits, is conveyed to brine clarification tanks, filtered and concentrated in 'vacuum' pans to throw out salt crystals, which are removed from the brine, washed with fresh brine to remove natural impurities, dried in rotary driers at 150 C., and mechanically screened. Salt of the desired granulation is mixed with the definite amounts of calcium phosphate to keep it free flowing, sodium bicarbonate and potassium iodide, and automatically packed. The sodium bicarbonate prevents loss of iodine during storage.

**Analysis** (submitted by manufacturer) —

	per cent
Moisture	less than 0.1
Calcium sulphate	0.22
Calcium chloride	0.04
Calcium phosphate	0.8
Magnesium chloride	0.04
Sodium bicarbonate	0.5
Sodium chloride (by difference)	98.3
Potassium iodide	0.023
pH	7.2

**Claims of Manufacturer**—For all table and cooking uses of salt. The added calcium phosphate tends to preserve its free running qualities. Used daily as the only salt on the table and in cooking, it richly supplements the iodine of diets deficient in that element and thus helps to protect against goiter caused by insufficient iodine in the diet.

#### STOKELY'S FOR BABY SPECIALLY PREPARED STRAINED SPINACH

SEASONED WITH SALT

**Manufacturer**—Stokely Brothers & Company, Inc., Indianapolis.

**Description**—Sieved spinach slightly seasoned with salt, largely retaining the natural minerals and vitamins.

**Manufacture**—Freshly cut spinach is carefully inspected and trimmed and any defective leaves are eliminated; it is washed under high pressure water sprays, blanched in boiling water for a minimum time necessary for softening, withdrawn, dipped into cool water, drained, comminuted, canned and processed as described for Stokely's Strained Green Beans (THE JOURNAL, May 26, 1934, p. 1762).

**Analysis** (submitted by manufacturer) —

	per cent
Moisture	92.7
Total solids	7.3
Ash	1.6
Sodium chloride	0.8
Fat (ether extract)	0.3
Protein (N × 6.25)	2.3
Reducing sugars as dextrose	0.4
Sucrose (copper reduction method)	0.0
Crude fiber	0.8
Carbohydrates other than crude fiber (by difference)	2.2
Alkalinity of ash (cc. normal acid per gram ash)	5.4
pH	6.5

**Calories**—0.2 per gram, 6 per ounce

**Vitamins**—The natural vitamin content is retained in large measure in the manufacturing process by the use of equipment and procedure which exclude incorporation of air; the vegetable material is exposed to steam only.

**Claims of Manufacturer**—Supplementary to the infant milk diet, and valuable for children and adults on soft diets. Has smooth consistency and supplies desirable bulk without roughness. The straining renders the nutrient content readily available for digestion. Scientifically prepared to retain in high degree the natural flavor, mineral and vitamin values. Seasoned to bring out full flavor and packed in enamel lined cans. Requires only warming for serving.

#### ANNA DALE BRAND EVAPORATED MILK

**Distributor**—Topeka Wholesale Grocery Co., Topeka, Kan.  
**Packer**—The Page Milk Company, Merrill Wis.

**Description**—Canned unsweetened sterilized evaporated milk, the same as Page Brand Evaporated Milk (Sterilized, Unsweetened), THE JOURNAL, May 30, 1931, page 1872.

## TYROSINURIA

Tyrosine is one of the long known amino acids derived from the breakdown of proteins. It is liberated in the digestive tract through the digestion of the albuminous foods and is readily conceivable as a product of the disintegration of protein in tissues whenever this occurs. Several amino acids may appear in the urine in any condition in which there is extensive tissue destruction. This explains the report of the occurrence of tyrosine in the urine as early as the middle of the last century by Frerichs and Stadel, when they observed this amino acid in a case of acute yellow atrophy of the liver. The appearance of tyrosine in the urine was subsequently reported by a number of clinical observers, but there is little doubt that some of these reports were cases of mistaken identity.<sup>2</sup> Consequently the view gradually developed that the frequency and amount of tyrosine excretion may not be as great as was formerly believed. One will find few recent textbooks of biochemistry or clinical chemistry that refer to the existence of tyrosinuria.

Renewed interest in the subject has been aroused by the studies of Lichtman and Sobotka<sup>3</sup> of the Mount Sinai Hospital in New York. They have replaced the old crystalloscopic method of examination of the urine by a biochemical procedure that permits the detection of free tyrosine in untreated urine on the basis of the enzymatic oxidation of this amino acid. A quantitative evaluation of the tyrosine is also made possible. The tyrosinase method of Lichtman and Sobotka reveals concentrations of 12.5 mg per hundred cubic centimeters. The advantages of this method over the Frerichs-Stadel crystalloscopic method are economy of time and labor, specificity and sensitivity.

The real importance of tyrosinuria for the clinician may be gathered from the fact that in Lichtman's studies the condition occurred in approximately 30 per

cent of the cases of disease of the gallbladder, bile passages and liver. It occurred most frequently in patients suffering from acute and subacute degeneration of the liver and less frequently in patients with malignant disease of the liver and bile passages, obstructive jaundice due to stone, and toxic (from arsphenamine and cinchophen) or catarrhal jaundice. In cases of pneumonia, leukemia, pernicious anemia and hyperthyroidism the results were negative. Five patients with jaundice complicating pneumonia, heart failure or leukemia had no tyrosine in the urine.

Years ago, Wells and Bassoe<sup>4</sup> pointed out the probability that any poison which does not directly cause death but which causes a severe injury to the liver cells without at the same time destroying the autolytic enzymes, so that the cells die and undergo rapid autolysis, may produce a condition identical with or similar to acute yellow atrophy. Whether these hypothetical poisons are produced by abnormal fermentation and putrefaction in the alimentary tract, or by a specific organism elaborating its poison in this location, is unknown. Tyrosinuria also appears in the presence of extrahepatic parenchymal autolysis. In degenerating carcinoma of the lung, tyrosine may be found in the sputum. It may appear in the urine if the degenerating process does not discharge its products through the bronchial tract.

The appearance of readily detectable amounts of tyrosine in the urine has always been considered an ominous sign. Lichtman has recovered massive amounts of tyrosine varying from 0.9 to more than 2 Gm from the urine in a period of twenty-four hours in acute cases of the disease. Massive excretion apparently indicates an acute diffuse degeneration of the liver. The excretion of tyrosine is continuous throughout the brief course of this illness. Temporary tyrosinuria, usually slight in amount, does not preclude recovery. According to Lichtman and Sobotka, observations on the rate of excretion of tyrosine are of diagnostic significance. Continuous massive tyrosinuria occurs only in cases of acute yellow atrophy with a rapid and fulminant course. Transitory minimal and moderate tyrosinuria occurs in cases of subacute atrophy of the liver, in degenerating neoplasm of the liver, in toxic degeneration of the liver and sometimes in obstructive jaundice of long standing due to stone. Inflammatory lesions of the bile passages do not of themselves give rise to tyrosinuria. Extrahepatic foci of autolysis, such as degenerating tumors of the lung or extensive sloughs of the skin, may give rise to minimal or moderate amounts of tyrosine in the urine. The transitory nature of minimal or moderate tyrosinuria is demonstrated by repeated tests. During the phase of recovery from degeneration of the liver, the products of parenchymal autolysis have already been absorbed and tyrosine vanishes from the urine.

<sup>4</sup> Wells, H. G. and Bassoe, Peter. *Acute Yellow Atrophy of the Liver*, *J. A. M. A.* 44: 685 (March 4) 1904.

The conditions just described should not be confused with what has lately been described by Medes<sup>5</sup> as tyrosinosis. This appears to be an "inborn error of metabolism" reminiscent of alkaptonuria. In tyrosinosis, tyrosine, dihydroxyphenylalanine, hydroxyphenylpyruvic acid and hydroxyphenyl acetic acid appear in the urine. Although only one case of this remarkable condition has been described thus far, its careful study by this investigator has given considerable information concerning several stages of the intermediary metabolism of tyrosine. Briefly stated, the condition described consists in a slowing up of the first steps of tyrosine metabolism and a complete stop at the stage of *p*-hydroxyphenylpyruvic acid.

### PRESSORECEPTOR NERVES AND THYROTOXIC CRISES

Von Cyon and Ludwig in 1866 showed that central stimulation of the sectioned superior cardiac nerve in rabbits caused a fall in the blood pressure and a slowing of the heart action. Two reflex effects resulted from electrical stimulation of this nerve: a vasodilating stimulation of the vasomotor center in the medulla oblongata and the slowing effect on the heart center. These authors named them "depressor" nerves. Koster, Tschermak and Schumacher demonstrated that these nerves terminated on the arch of the aorta and further designated them aortic nerves. The bilateral aortic or depressor nerves have been considered ever since to possess the function of reflex regulation of the circulation.

Hering<sup>1</sup> announced in 1924 that in addition to the two known depressors he had found two more nerves having the same action. These were the nerves of the carotid sinus bearing the anatomic name of *rami carotici nervi glossopharyngei*. These two sets of nerves appear to possess identical functional properties in that their receptor fibers are located in the arterial wall, the adequate stimulation of both manifests itself through endo-arterial blood pressure changes, and both give rise to two circulatory reflexes—vasodilatation and cardiac depression. They seem to constitute one functional unit. Koch<sup>2</sup> named them the pressoreceptor nerves of the circulation. In his experiments, Koch demonstrated that sectioning of all four pressoreceptor nerves in experimental animals resulted in a marked rise of blood pressure, which, when long continued, led to a permanently high blood pressure, cardiac hypertrophy and aortic sclerosis.

Braeucker<sup>3</sup> states that his anatomic studies of the pressoreceptor nervous system demonstrated that, con-

trary to the physiologic conception of the two nerves, the pressoreceptor nervous system is represented anatomically by a complex network of periarterial plexuses, which spread from the cardiac plexus over the arch of the aorta, the common carotid artery, its bifurcation and its branches. He therefore questions the specificity of the four nerves mentioned as constituting a separate functional unit. Careful experiments were performed in rabbits in which both cardiac branches of the superior laryngeal nerve as well as both carotid branches of the glossopharyngeus were sectioned at their origins. He succeeded in sectioning these with sufficient anatomic accuracy to avoid all injury to the neighboring periarterial plexuses and anastomosing branches. Nine animals survived, some of them living as long as 630 days. The blood pressure remained normal in all the animals. Sinus pressure on both sides caused a fall in the blood pressure, while clamping of both carotid arteries caused a rise in the blood pressure. The animals did not show cardiac hypertrophy or aortic or renal changes. Subsequent careful anatomic studies demonstrated that no regeneration of sectioned nerves took place. These results were at variance with the experiments of Koch, whose animals showed high blood pressure, cardiac hypertrophy and sclerosis of the aorta.

To throw light on this disparity, Braeucker in another series of experiments removed, in addition to the four pressoreceptor nerves, considerable areas of nerve plexuses of the internal carotid artery and of the common carotid artery. All the surviving animals showed high blood pressure, cardiac hypertrophy and sclerosis of the aorta. The more of the peripheral plexuses of the carotid that were destroyed, the more striking were the changes. Braeucker concludes that the afferent pressoreceptor paths are not limited to the four nerves but are parts of the peripheral vegetative nervous structure of the neck and the upper part of the thorax. The specific receptors are a part of the local periarterial nerve plexuses of the arch of the aorta and of the carotid sinus. According to Braeucker the same anatomic relations were found in dogs, cats and monkeys. In his anatomic studies in man he found the same relations as in animals, with the additional observation that the fibers of the pressoreceptor system here extend to the thyroid gland and form a plexus within the so-called thyroid capsule.

Jonnesco and Ionescu<sup>4</sup> had an opportunity, while operating on the sympathetic nerve in the neck, to section and stimulate the central end of the upper cardiac branch of the vagus as well as of the upper and the middle cardiac branches of the sympathetic. Stimulation of each of these produced a typical depressor effect, a fall in the blood pressure, slowing of the pulse and an alteration in the depth and rhythm of respiration. The pressoreceptor nerves can be stimu-

lated through mechanical and electrical stimuli, through changes in the arterial blood pressure and probably by chemical stimuli. These stimuli run centrally toward the centers of respiration, heart and vasomotor centers in the medulla. The possibility of reflex stimulation of bulbar centers at a distance has been established.

The significance of these facts in relation to surgery of the deep structures of the neck and especially to that of the thyroid gland is evident. The question arises as to the possible reflex effect of trauma to the nerve plexus of the thyroid capsule in the course of the delivery and resection of the gland. Braeucker believes that the frequent occurrence of sudden death of an animal in the course of his experimental work was of a reflex nature. He made the interesting observation that the grave symptoms of impending paralysis of bulbar centers developing in the course of his operative work on animals could be successfully combated by a prompt venesection. Braeucker made use of this observation in his clinical work and found that venesection was capable of averting what appeared to be imminent death in cases in which grave symptoms developed in the course of a thyroidectomy. He submits the histories of five patients with thyrotoxicosis, three of whom in the course of a thyroidectomy, and two several hours later, had grave disturbances of respiration and of cardiac and vasomotor functions. A prompt venesection of the anterior jugular vein had the immediate effect of completely relieving these symptoms. Venesection was effective in two cases in which signs of involvement of the bulbar centers developed some time after the operation. These so-called postoperative thyroid crises were believed to be caused by the flooding of the organism with thyroxine. Later, the opposite theory was suggested that the reaction was the result of sudden thyroxine deprivation of the organism. There was no experimental proof for either theory. These late crises may well be caused by accumulated chemical irritation of bulbar centers, the result of acidosis. Braeucker considers that the sudden death occurring in the course of a thyroidectomy, and the postoperative thyrotoxic crises, are reflex phenomena resulting from irritation of the pressoreceptor nerves. A timely venesection, by lowering the blood pressure, is capable of reflexly diminishing the irritative stimuli in the entire pressoreceptor system and so averting imminent death. To avoid undue irritation of the pressoreceptor paths in the course of a thyroidectomy, this author advises the use of general anesthesia aided by local procaine hydrochloride blocking of the pressoreceptor paths. He deposits procaine hydrochloride solution at the site of bifurcation of the common carotid artery, about the stem of the vagus (lower third of the ganglion nodosum), and into the area of the upper cervical ganglion and the stellate ganglion. Dangerous reactions occurring in spite of these measures are best treated by a prompt venesection.

## Current Comment

### OXYGEN INHALATION AND ATHLETIC ACTIVITY

In the Olympic games held in California in 1932 the Japanese swimming team inhaled oxygen for five minutes about half an hour before competition. The charge was made that such inhalations were unethical and that they were largely responsible for the successful showing of the Japanese competitors. Karpovich<sup>1</sup> has recently made available the reports of an investigation of the possibilities. His experiments follow others which establish fairly well the fact that the breathing of oxygen is an immediate aid to an athletic performance if taken just before exercise. Leonard Hill and Martin Flack found in 1910 that preliminary inhalation of oxygen is useful in running short distances only. Karpovich tested the effects of two deep inhalations of pure oxygen immediately before plunging into water. In eleven out of seventeen cases, men who did this were able to break their own unofficial records. Moreover, of six who could not break their own records, four did not follow instructions and exhaled the oxygen before striking the water. However, swimmers who inhaled oxygen for a period of from three to five minutes and discontinued it from four to five minutes before a hundred yard swim found that the inhalation had no noticeable effect on the speed of swimming. It was found that the inhalation of oxygen after any athletic activity hastens recovery. Karpovich concludes that oxygen taken immediately before strenuous exercise does benefit the athlete but that oxygen taken a long interval before the exercise has little, if any, effect. He explains the value of oxygen inhalations immediately before swimming by the fact that respiratory movements retard speed and that oxygen inhalations make respiratory movements unnecessary for a certain length of time. The interesting fact was established that after three inhalations of oxygen a person can hold the breath in a lying position up to six minutes and thirty seconds.

### THE WOMAN'S AUXILIARY

The business program and the program of women's entertainment for the Woman's Auxiliary at the Cleveland session indicated how far the Auxiliary has advanced in rendering aid to organized medicine and in developing the medical consciousness of its members. Committees are actively studying problems of public relations, legislation and similar questions in relationship to medical affairs. In many states the Woman's Auxiliary has been an invaluable aid in developing circulation for *Hygeia*. Moreover, the Woman's Auxiliary cooperated fully with the local women's entertainment committee in developing programs of interest and entertainment for all women visitors. The members of the Woman's Auxiliary are taking in earnest their responsibilities as a body associated with organized medicine and have more than justified the time and money spent on their efforts.

# PROCEEDINGS OF THE CLEVELAND SESSION

## MINUTES OF THE EIGHTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT CLEVELAND, JUNE 11 15, 1934

(Concluded from page 2207, volume 102)

### MINUTES OF THE SECTIONS

#### SECTION ON PRACTICE OF MEDICINE

WEDNESDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr C T Stone, Galveston, Texas

Dr Harlow Brooks, New York, read a paper on "The Cause of Death in Adult Pneumonia" Discussed by Drs James H Meaus, Boston, L J Moorman, Oklahoma City, Maxwell Finland, Boston, Robert G Torrey Philadelphia, A L Barach, New York, and Harlow Brooks, New York

Dr Harry G Wood, Rochester Minn, read a paper on "Congenital Polycystic Disease of the Lungs" Discussed by Drs L J Moorman, Oklahoma City James L Dubrow Des Moines, Iowa, J J Singer, St Louis, and Harry G Wood, Rochester, Minn

Dr Jonathan C Meakins, Montreal read a paper on "The Treatment of Emphysema" Discussed by Drs Adolphus Knopf, New York, and Dr Jonathan C Meakins, Montreal

Dr Walter L Bierring Des Moines, Iowa, introduced the Frank Billings lecturer for this year, Dr James B Herrick, Chicago, who read a paper on "The Practitioner of the Future"

Dr Ralph A Kinsella, St Louis read a paper on "Epidemic Encephalitis" Discussed by Dr J P Leake, Washington, D C

Drs Herrmann L Blumgart and David D Berlin, Boston, presented a paper on "A Review of Eighteen Months' Experience with Total Ablation of the Thyroid for Angina Pectoris and Congestive Failure" Discussed by Drs Samuel A Levine, Boston James H Means, Boston, R R Snowden, Pittsburgh William B Porter Richmond Va W O Thompson, Chicago George M Curtis Columbus Ohio Emanuel Libman New York Edmund Horgan, Washington, D C, and Herrmann L Blumgart, Boston

THURSDAY, JUNE 14—AFTERNOON

Dr Alfred Friedlander, Cincinnati, read a paper on "Recognition of Types of Arteriosclerosis by Oscillometry" Discussed by Drs Carl J Wiggers, Cleveland, and Alfred Friedlander, Cincinnati

Dr Lea A Riely, Oklahoma City read a paper on "Diabetic Complications" Discussed by Drs Priscilla White, Boston S Edward King, New York Henry J John, Cleveland, Henry W Meyerding Rochester, Minn, W S Collens, Brooklyn, and Lea A Riely, Oklahoma City

Dr L M S Miner Boston, read a paper on "The Relation of Dentistry to Medicine"

The following papers were read as a symposium on "The Treatment of Chronic Arthritis"

Dr Ernest E Irons, Chicago "General Considerations"

Dr Russell L Cecil New York "Medical Treatment"

Dr Loring T Swaim, Boston "Orthopedic and Physical Therapeutic Treatment"

These three papers were discussed by Drs Walter Bauer, Boston Linn J Boyd, New York, W Paul Holbrook, Tucson, Ariz, Maurice F Lautman, Hot Springs Ark, S C Woldenberg, New York Heinrich F Wolf New York, William J Kerr, San Francisco, H M Davidson, Atlanta, Ga, S Adolphus Knopf, New York James Patterson, Scarsdale, N Y and A S Gordon, Brooklyn

FRIDAY, JUNE 15—AFTERNOON

The following officers were elected chairman, Dr George R Minot, Boston, vice chairman, Dr M A Blankenhorn, Cleveland, secretary, Dr William J Kerr, San Francisco, delegate, Dr J E Paulin Jr, Atlanta, Ga, alternate, Dr E C Irons, Chicago, executive committee, Dr Reginald Fitz, Boston, Dr C T Stone, Galveston, Texas, Dr George R Minot, Boston

Drs Harold W Jones and Leandro M Tocantins, Philadelphia, presented a paper on "Treatment of Hemophilia"

Drs Edward C Reifenstein and Ellery G Allen, Syracuse, N Y, presented a paper on "Treatment of Hemolytic Jaundice by Liver Extract"

Drs Cyrus C Sturgis and S M Goldhamer, Ann Arbor, Mich, presented a paper on "The Occurrence and Treatment of Neurologic Changes in Pernicious Anemia"

These three papers were discussed by Drs Adolph Sachs, Omaha, Wann Langston, Oklahoma City, V P Sydenstricker, Augusta, Ga, Russell L Haden, Cleveland, Jackson Blair, Cleveland, M A Blankenhorn, Cleveland, Leandro M Tocantins Philadelphia S M Goldhamer, Ann Arbor, Mich, and Ellery G Allen, Syracuse, N Y

Dr C T Stone, Galveston, Texas, read the chairman's address, entitled "Mortality from Heart Disease, a Challenge"

Dr Louis E Viko, Salt Lake City, read a paper on "Prognosis in Arteriosclerotic Heart Disease" Discussed by Drs Walter L Bierring, Des Moines, Iowa, R Wesley Scott, Cleveland, and Louis E Viko, Salt Lake City

Dr Fred H Kruse, San Francisco, read a paper on "The Syndrome of Hypertonic and Atonic Colopathy" Discussed by Drs Lowellys F Barker, Baltimore, W L Palmer, Chicago, E L Eggleston, Battle Creek, Mich, William Lintz, Brooklyn, and Fred H Kruse, San Francisco

#### SECTION ON SURGERY, GENERAL AND ABDOMINAL

WEDNESDAY, JUNE 13—MORNING

The meeting was called to order at 9 10 by the chairman, Dr Harold Brunn, San Francisco

Dr R L Payne, Norfolk, Va, read a paper on "Femoral Hernia Operative Repair by Fascial Sutures" Discussed by Drs H W Cave, New York, and F W Bailey, St Louis

Dr Claude S Beck, Cleveland, read a paper on "Contusions of the Heart" Discussed by Drs R L Sanders, Memphis, Tenn, and Joseph T Wearn, Cleveland

On motion of Dr Frank H Lahey, Boston, seconded by Dr M G Seelig, St Louis, it was voted to nominate Dr H H Loucks of Peiping Union Medical College, Peiping, China, for Associate Fellowship

Dr Waltman Walters, Rochester, Minn, read a paper on "Surgical Treatment of Extensive Malignant Lesions of the Stomach" Discussed by Drs Frank H Lahey, Boston Gatewood, Chicago, J T Mason, Seattle, J Shelton Horsley, Richmond, Va, J W Thompson, St Louis, and Waltman Walters, Rochester, Minn

Dr Hugh H Trout, Roanoke, Va, read a paper on "The Treatment of Perforated 'Peptic Ulcers'" Discussed by Drs Roy D McClure, Detroit, Edward J Donovan, New York,

J M Donald, Birmingham, Ala., and Hugh H Trout, Roanoke, Va

Drs Roscoe R Graham and Frederick I Lewis, Toronto, presented a paper on "The Recognition and Treatment of Jejunal Ulceration" Discussed by Drs Dean Lewis, Baltimore, Donald C Balfour, Rochester, Minn., and Roscoe R Graham, Toronto

Dr William F Rienhoff Jr, Baltimore, read a paper on "The Surgical Treatment of Carcinoma of the Lungs and Bronchi" Discussed by Drs Evarts A Graham, St Louis, E F Butler, Elmira, N Y, Clyde I Allen, Detroit, and William F Rienhoff Jr, Baltimore

The members arose in silent tribute to the memory of Dr Carl A Hedblom

#### THURSDAY, JUNE 14—MORNING

Dr Harold Brunn, San Francisco, read the chairman's address, entitled "Lung Abscess"

Dr J Shelton Horsley, Richmond, Va., read a paper on "The Bearing of Certain Physiologic Facts on Gastro-Intestinal Surgery" Discussed by Dr George W Crile, Cleveland

Drs John F Gile and John P Bowler, Hanover, N H, presented a paper on "The Management of Perforated Appendicitis"

Dr Fred A Collier, Ann Arbor, Mich., read a paper on "The Treatment of Peritonitis Associated with Appendicitis"

These two papers were discussed by Drs Alton Ochsner, New Orleans, Le Grand Guerry, Columbia, S C, C F Dixon, Rochester, Minn., R J Behan, Pittsburgh, George A Hendon, Louisville, Ky, F F Lawrence, Columbus, Ohio, and Fred A Collier, Ann Arbor, Mich

Dr J C Bloodgood, Baltimore, read a paper on "Diagnosis and Treatment of Tumors of the Breast, Clinically Benign and Clinically Malignant, as Based on Biopsy" Discussed by Drs Irvin Abell, Louisville, Ky, Max Cutler, Chicago, and J C Bloodgood, Baltimore

Dr Thomas E Jones, Cleveland, read a paper on "Intestinal, Rectal and Bladder Complication Resulting from Prolonged Radium and X-Ray Irradiation for Malignant Conditions of the Pelvis Surgical Treatment" Discussed by Dr George G Ward, New York

#### FRIDAY, JUNE 15—MORNING

The following officers were elected chairman, Dr John L Yates, Milwaukee, vice chairman, Dr Robert Scott Dinsmore, Cleveland, secretary, Dr Howard M Clute, Boston, delegate, Dr Fred W Rankin, Lexington, Ky, alternate, Dr Lloyd Noland, Fairfield, Ala

Drs I S Ravdin and C G Johnston, Philadelphia, presented a paper on "Alterations of Function in Biliary Tract Disease"

Dr A C Ivy, Chicago, read a paper on "Physiologic Principles to Be Considered in the Therapy of Biliary Tract Disease The Physiology of the Gallbladder, Some Principles to Be Considered in Therapy"

Dr Evarts A Graham, St Louis, read a paper on "A Consideration of the Stoneless Gallbladder"

These three papers were discussed by Drs Donald Guthrie, Sayre, Pa., Urban Maes, New Orleans, George A Hendon, Louisville, Ky, I S Ravdin, Philadelphia, and Evarts A Graham, St Louis

Dr C F Dixon, Rochester, Minn., read a paper on "Carcinoma of Cecum What Are the Chances for Cure?" Discussed by Drs Jerome M Lynch, New York, and J W Thompson, St Louis

Dr R B Cattell, Boston, read a paper on "Surgical Treatment of Ulcerative Colitis" Discussed by Drs F R Peterson, Iowa City, and Alfred A Strauss, Chicago

Drs Richard H Miller and Horatio Rogers, Boston, presented a paper on "Present Status of Tetanus, with Special Regard to Treatment" Discussed by Drs Frederick W Taylor, Indianapolis, and Richard H Miller, Boston

### SECTION ON OBSTETRICS, GYNECOLOGY AND ABDOMINAL SURGERY

#### WEDNESDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman Dr Joseph B De Lee, Chicago

The following papers were read as a symposium on "Modern Indications for Therapeutic Abortion"

Dr Clarence O Cheney, New York "Neuropsychiatry"

Dr Henry P Wagener, Rochester, Minn "Ophthalmology,"

Discussed by Dr Arthur J Bedell, Albany, N Y

Dr W W Herrick, New York "Nephrology" Discussed by Dr Robert D Mussey, Rochester, Minn

Dr Harold E B Pardee, New York "Cardiology" Discussed by Dr Burton E Hamilton, Boston

Dr F M Pottenger, Monrovia, Calif "Pulmonology" Discussed by Dr Fred L Adair, Chicago

These five papers were discussed by Drs Frederick J Taussig, St Louis, Joseph B De Lee, Chicago, Misch Casper, Louisville, Ky, Clarence O Cheney, New York, Henry P Wagener, Rochester, Minn, W W Herrick, New York, Harold E B Pardee, New York, and F M Pottenger, Monrovia, Calif

#### THURSDAY, JUNE 14—AFTERNOON

Drs R A Bartholomew and E D Colvin, Atlanta, Ga, presented a paper on "The Advantages of Paraldehyde as a Basic Amnesic Agent in Obstetrics" Discussed by Drs Harold H Rosenfeld, Boston, H F Kane, Washington, D C, and R A Bartholomew, Atlanta, Ga

Dr B P Watson, New York, read a paper on "Practical Measures in the Prevention and Treatment of Puerperal Sepsis" Discussed by Drs J C Litzenberg, Minneapolis, Joseph B De Lee, Chicago, A F Lash, Chicago, J I Hofbauer, Cincinnati, William H Vogt, St Louis, and B P Watson, New York

Dr Joseph B De Lee read the chairman's address

Dr Lyle G McNeile, Los Angeles, read a paper on "The Conservative Treatment of Eclampsia" Discussed by Drs Paul Titus, Pittsburgh, and Albert Holman, Portland, Ore.

Dr M Edward Davis, Chicago, read a paper on "Pregnancy Changes in the Vaginal Epithelium in Relation to the Vaginal Cycle" Discussed by Drs Fred L Adair, Chicago, and M Edward Davis, Chicago

#### FRIDAY, JUNE 15—AFTERNOON

On motion regularly made and seconded it was voted to refer a letter dated May 31, 1934 from Dr T F Murphy, chief statistician for vital statistics, Department of Commerce Bureau of Census, Washington, D C, to the Standing Committee on Maternal Welfare

The chairman read the following report of the Committee on Maternal Welfare which was adopted and the secretary authorized to order a continuation of the committee

The Section Committee on Maternal Welfare reports progress Your representatives are now a part of a formally incorporated organization known under the name of the American Committee on Maternal Welfare The continuation of the section committee is recommended

RUDOLPH W HOLMES  
ROBERT MUSSEY  
FRED L ADAIR

The following officers were elected chairman, Dr James R McCord, Atlanta, Ga, vice chairman, Dr A J Skeel, Cleveland, secretary, Dr E D Plass, Iowa City, delegate, Dr George Gray Ward, New York, alternate, Dr J P Pratt, Detroit

Dr Ralph L Barrett, New York, read a paper on "Electrocoagulation of Cervical Erosions and Endocervicitis in the Late Puerperium" Discussed by Drs Joseph B De Lee, Chicago, A H Curtis, Chicago, and Ralph L Barrett, New York

Dr J I Hofbauer, Cincinnati, read a paper on "Factors Predisposing to Carcinoma of the Uterus" Discussed by Drs J P Greenhill, Chicago, Emil Novak, Baltimore, and J I Hofbauer, Cincinnati

Dr Chester M Echols, Milwaukee, read a paper on "Comments on One Hundred Cases of Ectopic Pregnancy Encoun-

tered in Private Practice' Discussed by Drs Joseph D Heinrich Cincinnati, Joseph B De Lee, Chicago and W H Wier, Cleveland

Dr Henry Schmitz, Chicago, read a paper on "Early Histologic Diagnosis of Carcinoma of the Uterine Cervix" Discussed by Drs Emil Novak, Baltimore I C Bloodgood, Baltimore, Fred Wetmorell, Syracuse, N Y and Henry Schmitz, Chicago

Drs T O Muncies and J Duran Miller Grand Rapids, Mich, presented a paper on "Demonstration of the Endometrium in Relief with Thorium Dioxide Sol" No discussion

## SECTION ON OPHTHALMOLOGY

WEDNESDAY, JUNE 13—MORNING

The meeting was called to order at 9:10 by the vice chairman Frank E Burch, St Paul

Vice Chairman Burch expressed regret at the loss of Dr William C Funnoff, chairman, and it was moved by Dr Frederick H Verhoeff, Boston, and seconded by Dr L J Goldbach, Baltimore, that a message of sympathy be sent from the section to his widow and family. The members stood in silence for one minute.

The Secretary, for the late Dr William C Funnoff, Denver, read the following resolutions for submission to the House of Delegates:

WHEREAS It has come to the attention of the officers of the Section on Ophthalmology that some hospitals employ optometrists to prescribe glasses and

WHEREAS The members of the section are convinced that this practice is not to the best interest of the patient and

WHEREAS The only reason for such an unprofessional method seems to be monetary reward to the hospital and

WHEREAS The younger ophthalmologists need practice in refraction which is best secured under the direction of skillful physicians devoting themselves to the treatment of disease of the eye be it

Resolved That the Section on Ophthalmology of the American Medical Association hereby registers its disapproval of the employment of optometrists by hospitals and further be it

Resolved That the House of Delegates of the American Medical Association be urged to institute the necessary measures to stop this pernicious invasion of the practice of medicine

The resolutions were adopted by the section, and the delegate was advised to submit them to the House of Delegates

The following papers were read as a symposium on "Treatment of Retinal Detachment by Electrical Coagulation"

Dr Mark J Schoenberg, New York "Clinical Experiences with the Diathermic Treatment of Retinal Detachments"

Dr Clifford B Walker, Los Angeles "New Devices and Modification for Diathermic Operation and Localization in Separation of the Retina"

These two papers were discussed by Drs Arnold Knapp, New York, Harry S Gradle, Chicago, Dohrmann K Pischel, San Francisco, L C Peter, Philadelphia, Harvey E Thorpe, Pittsburgh, Oscar Wilkinson, Washington, D C, Mark J Schoenberg, New York, and Clifford B Walker, Los Angeles

Dr Albert Louis Brown, Cincinnati, read a paper on "Bacteriologic and Immunologic Considerations of Chronic Uveitis" Discussed by Drs William Zentmayer, Philadelphia, Alan C Woods, Baltimore, Jonas S Friedenwald, Baltimore, Conrad Berens, New York, and Albert Louis Brown, Cincinnati

Dr W H Wilmer, Baltimore, introduced Dr Edward Jackson, Denver, who was attending his fiftieth annual session of the American Medical Association

Dr Edward Jackson, Denver, read the report of the Committee on Definition of Blindness. On motion by Dr Conrad Berens, New York, seconded by Dr Frederick H Verhoeff, Boston, the report was sent to the House of Delegates

Dr Charles M Swab, Omaha, read a paper on "The Ocular Lesions Resulting from Thallium Acetate Poisoning as Determined by Experimental Research" Discussed by Drs Edward Jackson, Denver, George H Stine, Colorado Springs, Colorado, Arthur J Bedell, Albany, N Y, and Charles M Swab, Omaha

Dr Edward Stieren, Pittsburgh, read a paper on "Sarcoma of the Uveal Tract Following Trauma" Discussed by Drs Laura A Lane, Minneapolis, Frederick H Verhoeff, Boston, Leo L Mayer, Chicago, Adolph O Pfingst, Louisville, Ky, William L Benedict, Rochester, Minn, and Edward Stieren, Pittsburgh

THURSDAY, JUNE 14—MORNING

Dr George P Guibor, Chicago, read a paper on "Practical Details in the Orthoptic Treatment of Strabismus" Discussed by Drs Lawrence T Post, St Louis, Oscar Wilkinson, Washington, D C, Edward C Ellett, Memphis, Tenn, and George P Guibor, Chicago

Dr James Watson White, New York, read a paper on "Routine Muscle Examination in Its Practical Application" Discussed by Drs Edward C Ellett, Memphis, Tenn, Morris Davidson, New York, and James Watson White, New York

Dr John E L Keyes, Youngstown, Ohio, read a paper on "Observations of Four Thousand Optic Foramina in Human Skulls of Known Origin" Discussed by Drs N W Ingalls, Cleveland, Raymond L Pfeiffer, New York, and John E L Keyes, Youngstown, Ohio

Drs Alfred W Adson and William L Benedict, Rochester, Minn, presented a paper on "Hemangio-Endothelioma of the Orbit, Removal Through Transcranial Approach" Discussed by Drs Edmund B Sprath, Philadelphia, C S O'Brien, Iowa City, William L Benedict, Rochester, Minn, and Alfred W Adson, Rochester, Minn

Dr Walter I Lillie, Philadelphia, read a paper on "Unilateral Central and Annular Scotoma Produced by Fracture of the Optic Canal: Report of Two Cases" Discussed by Drs Webb W Weeks, New York, Walter I Lillie, Philadelphia, and Alfred W Adson, Rochester, Minn

Dr Benjamin Rones, Baltimore, read a paper on "Anterior Lenticulus" Discussed by Drs Clyde A Clapp, Baltimore, and Benjamin Rones, Baltimore

At the Demonstration Session the following were shown

Dr Conrad Berens, New York, presented a test for fusion and a fusion spectacle, also a Clinical Ophthalmic Ergograph

Dr Harvey E Thorpe, Pittsburgh, presented an Ocular Endoscope

Dr George P Guibor, Chicago, presented New Fusion Training Cards for Orthoptic Training

Dr Morris Davidson, New York, presented a useful test in squint cases

Dr Leo Mayer, Chicago, presented a Strabismometer

FRIDAY, JUNE 15—MORNING

The following officers were elected: chairman, Dr Arthur J Bedell, Albany, N Y, vice chairman, Dr C A Clapp, Baltimore, secretary, Parker Heath, Detroit, executive committee, Dr F H Verhoeff, Boston, Dr F E Burch, St Paul, and Dr Arthur J Bedell, Albany, N Y

The report of the Committee on Compensation Tables was accepted and the committee continued

The report of the Committee on Optics and Visual Physiology was accepted

The report of the Committee on the Knapp Testimonial Fund was accepted

The report of the Committee on American Board of Ophthalmology was accepted

The report of the Committee on Pathology was accepted and the committee continued

The report of the Committee to Cooperate with the National Committee for the Prevention of Blindness was accepted and the committee continued

The report of the Committee for Scientific Exhibit from the Section was accepted

The report of the Committee on Nomenclature was accepted and the committee continued

Dr Emory Hill reported as delegate to the House of Delegates

The report of the Committee on Museum of Ophthalmic History was accepted and the committee continued

The report of the Committee on Ophthalmic Standards was accepted and the committee continued as a standing committee

The report of the Executive Committee was accepted

The following members were nominated for the Committee on Awarding the Knapp Medal: Drs Arnold Knapp, Edmond E Blaauw and Walter Parker

Dr Bennett Y Alvis, St Louis, read a paper on "Blepharochalasis" Discussed by Drs Edward B Heckel, Pittsburgh, Leo L Mayer, Chicago, Edward Stieren, Pittsburgh, and Bennett Y Alvis, St Louis

Dr C S O'Brien, Iowa City, read a paper on "Diabetic Cataract Incidence and Morphology in One Hundred and Three Young Diabetic Patients" Discussed by Drs Arnold Knapp, New York, Sanford Gifford, Chicago, Edmond C Blaauw, Buffalo, and C S O'Brien, Iowa City

Dr Phillips Thygeson, Iowa City, read a paper on 'Etiologic Diagnosis of Conjunctivitis' Discussed by Drs Frederick H Verhoeff, Boston, Edward Jackson, Denver, and Phillips Thygeson, Iowa City

Dr T L Terry, Boston, read a paper on Pulsating Exophthalmos Due to Internal Carotid-Jugular Aneurysm The Use of Thorium Dioxide in Localization Discussed by Drs Adolph O Pfingst, Louisville, Ky Mont R Reid Cincinnati, and T L Terry, Boston

Dr Alfred Cowan, Philadelphia read a paper on Some Factors Concerned in the Correction of Aphakia Discussed by Drs Derrick T Vail Jr, Cincinnati, Frederick Verhoeff, Boston, and Alfred Cowan, Philadelphia

## SECTION ON LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY

WEDNESDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr William P Wherry, Omaha

On motion of Dr L W Dean, St Louis, seconded by Dr John W Carmack, Indianapolis, it was voted to nominate Dr George W Christiansen Detroit, for Associate Fellowship

Dr William P Wherry, Omaha read the chairman's address

Dr L W Dean, St Louis, read a paper on "The Tonsils, Their Function and Indications for Their Removal" Discussed by Drs Frank R Spencer Boulder Colo, Edward Clay Mitchell, Memphis, Tenn Virgil J Schwartz, Minneapolis, and L W Dean St Louis

Dr Frank J Novak Jr, Chicago read a paper on "The Structure of the Secondary Nodule of the Tonsil" Discussed by Drs John B McMurray Washington Pa, and J D Heitger, Louisville, Ky

Dr Gordon B New Rochester Minn read a paper on "The Use of Reconstructive Surgery in Certain Types of Deformities of the Face" Discussed by Drs Samuel Iglauer, Cincinnati Fielding O Lewis, Philadelphia, George B Jobson, Franklin, Pa Claire L Straith Detroit, Myron Metzenbaum, Cleveland, and Gordon B New Rochester Minn

Drs R A Kern and H P Schenck, Philadelphia, presented a paper on 'The Importance of Allergy in the Etiology and Treatment of Nasal Mucous Polyps'

Dr Harold G Tobey, Boston read a paper on "An Attempt to Correlate the Various Theories of Vasomotor Disturbances of the Nasal and Bronchial Tracts" Discussed by Drs Warren T Vaughan, Richmond Va, Ernest M Seydell, Wichita, Kan Jonathan Forman Columbus Ohio, Harry L Baum, Denver, Oscar Wilkinson Washington D C, H P Schenck Philadelphia and Harold G Tobey Boston

THURSDAY JUNE 14—AFTERNOON

Dr Robert F Ridpath Philadelphia read a paper on 'Agranulocytic Angina or Malignant Neutropenia' Discussed by Drs James B Costen St Louis Claude L LaRue Shreveport, La John J Shea Memphis Tenn William H Gordon, Detroit Henry N Harkins Chicago and Robert F Ridpath Philadelphia

Drs George M Coates, Matthew S Ersner and David Myers, Philadelphia read a paper on 'X-Ray Changes in the Petrous Portion of the Temporal Bone Without Clinical Manifestations' Discussed by Drs John W Carmack Indianapolis B H Nichols Cleveland Henry K Taylor New York M C Myerson, New York, and Matthew S Ersner, Philadelphia

Dr Clarence H Smith New York read a paper on 'Practical Points in the Radical Mastoid Operation' Discussed by Drs Harry P Cahill Boston Kenneth M Day Pittsburgh, Horace Newhart Minneapolis George E Shambaugh Jr, Chicago and Clarence H Smith New York

Dr Anderson C Hilding Duluth Minn read a paper on 'Changes in the Lysozyme Content of the Nasal Secretion During Colds' A Preliminary Report Discussed by Drs

Dean M Lierle, Iowa City, T C Galloway, Evanston Ill, and Anderson C Hilding, Duluth

Dr H Marshall Taylor, Jacksonville, Fla, read a paper on "Prenatal Medication as a Possible Etiologic Factor of Deafness in the New-Born" Discussed by Drs John H Foster, Houston, Texas, Robert D Mussey, Rochester, Minn, Burt R Shurly, Detroit, R G Reaves, Knoxville, Tenn, and H Marshall Taylor, Jacksonville

Dr Ralph A Tenton, Portland, Ore, read a paper on 'Diagnostic Factors Concerning Herpes Zoster Oticus' Discussed by Drs Harris P Mosher, Boston Gordon F Harkness Davenport, Iowa Harris H Vail, Cincinnati, and Ralph A Tenton Portland, Ore

Dr Romeo A Luongo, Philadelphia, presented a new mastoid retractor with light attachment, also a set of hand retractors and periosteal elevators for the external pansinus operation

Dr Louis K Pitman, New York, presented the nasopharyngoscope and its operating attachments, an instrument to advance a soft rubber catheter automatically into the lung, also a self-angulating snare

Dr Horace Newhart, Minneapolis, presented a tonsil snare a tonsil probe and an audiogram blank

Dr George B Jobson, Franklin, Pa, presented a set of instruments for electrosurgical tonsillectomy

Dr R G Reaves Knoxville Tenn, presented new instruments for irrigating antrums through the middle meatus

Drs Mervin C Myerson, Herman Rubin and Joseph G Gilbert New York, presented instruments for operation on the petrous pyramid

FRIDAY, JUNE 15—AFTERNOON

The following officers were elected chairman, Dr John J Shea, Memphis Tenn, vice chairman Dr John B McMurray, Washington, Pa secretary Dr John W Carmack, Indianapolis

The report of the Executive Committee was presented by Dr Harris P Mosher Boston, and accepted

Dr William V Mullin read the report of the Examining Board in Otolaryngology which was accepted

During 1933 two examinations were held, one in Milwaukee just prior to the American Medical Association meeting, and one in Boston, just previous to the meeting of the American Academy of Ophthalmology and Otolaryngology During the year, 151 candidates were examined and 136 were certificated

The board was active in establishing a new advisory board which will serve as a coordinating body for all the specialties This advisory board is working in conjunction with the Council on Medical Education and Hospitals of the American Medical Association and has set up twelve specialties in medicine for which boards will be organized

The following branches of medicine now have examining boards that are functioning ophthalmology otolaryngology obstetrics and gynecology dermatology pediatrics and radiology

Dr Chevalier Jackson read a report on Lye Legislation, which was accepted He requested that Dr Clyde Brooks, New Orleans replace the late Dr R C Lynch on the committee

Dr H Marshall Taylor read the report on Swimming which was accepted and the committee retained

Dr Edmund Prince Fowler New York read a paper on Hearing Reclamation and Preservation in the Moderately Deafened Child Management and Treatment Based on Ten Years of Clinical and Laboratory Research Discussed by Drs M Raymond Kendall Cleveland Horace Newhart Minneapolis Austin A Hayden Chicago Wendell C Phillips, New York and Edmund Prince Fowler New York

Dr O Jason Dixon Kansas City, Mo read a paper on Experimental Studies in Vascular Repair A Report of Two Hundred Experimental Studies Discussed by Drs Mont R Reid Cincinnati Lyman G Richards, Boston and O Jason Dixon Kansas City Mo

Dr Howard V Dutrow Dayton Ohio read a paper on Conservative Surgical Treatment of Hypertrophic Rhinitis Discussed by Drs J A Pratt Minneapolis H M Goodyear Cincinnati Clarence W Engler Cleveland, and Howard V Dutrow Dayton Ohio

Dr M M Cullom Nashville Tenn, read a paper on 'The Association of Middle Ear Infection with Sinus Disease'

Discussed by Drs Lamar G Richards Boston, Gordon D Hoople, Syracuse, N Y George E Shrimbaugh Jr, Chicago S S Evans, Memphis Tenn, J A Pratt, Minneapolis, and M M Cullom Nashville

Dr Edward King Cincinnati read a paper on "An X-Ray Study of the Maxillary Antrum Before and After Operation" Discussed by Drs Second H Large Cleveland, Louis L Brown Akron, Ohio Anderson C Hilding, Duluth, Minn, and Harris H Van Cincinnati

Dr Walter H Theobald Chicago read a paper on "New Adaptation of X-Ray Prints and Slides Giving Stereoscopic Effect" Discussed by Drs Ira Frank Chicago, O Jason Dixon Kansas City, Mo, and Walter H Theobald, Chicago

## SECTION ON PEDIATRICS

WEDNESDAY, JUNE 13—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr Alfred A Walker Birmingham Ala

Drs Henry I Gerstenberger, A J Horesh J D Nourse and A L Van Horn Cleveland presented a paper on "Further Studies on Tungsten Filament Radiation (Dural Purpose Lighting)" Discussed by Drs A Grieme Mitchell Cincinnati, John S Coulter, Chicago and Henry J Gerstenberger, Cleveland

Dr Arvid Wallgren Goteborg Sweden read a paper on "The Value of the Calmette Vaccination in Prevention of Tuberculosis in Childhood"

Dr J A Myers, Minneapolis read a paper on "The Effect of Initial Tuberculous Infection on Subsequent Tuberculous Lesions" Discussed by Drs Horton R Casparis Nashville, Tenn W Ambrose McGee Richmond Va and J A Myers Minneapolis

Dr Stewart H Clifford Boston read a paper on "The Application of Determinations of Fetal Size in Utero to the Problem of Reducing the Premature Infant" Discussed by Drs Fred L Adair Chicago Julius H Hess Chicago, and Stewart H Clifford Boston

Drs Clifford G Grulee and Heyworth N Sanford, Chicago and Paul H Herron, Spokane Wash presented a paper on "A Study of the Influence of Breast and Artificial Feeding on the Morbidity and Mortality of Twenty Thousand Infants" Discussed by Drs Frank C Neff Kansas City Mo Paul H Herron Spokane, Wash Jay I Durand Seattle Berthold Fleischmann New York and Clifford G Grulee Chicago

Drs Charles Hendee Smith Irving Graef and Elizabeth H T Andrews New York, presented a paper on "The Pathology of Pneumonia in Infancy" Discussed by Drs Frank W Konzelmann, Philadelphia Karl E Kassovitz, Milwaukee, Clifford Sweet, Oakland, Calif and Charles Hendee Smith, New York

THURSDAY JUNE 14—MORNING

Dr Lewis W Hill Boston, read a paper on "Chronic Atopic Eczema (Neurodermatitis) in Childhood" Discussed by Drs Marion B Sulzberger New York, J Victor Greenebaum, Cincinnati, George Piness, Los Angeles Charles Hendee Smith New York and Lewis W Hill Boston

Dr Alfred A Walker Birmingham Ala read the chairman's address entitled "One Dose Alum Toxoid in Diphtheria Immunization"

Dr Albert D Kaiser Rochester N Y read a paper on "Factors That Influence Rheumatic Disease in Childhood" Discussed by Drs Albert J Bell Cincinnati, and Jesse R Gerstley, Chicago

Dr Robert L Schaefer Detroit read a paper on "Therapeutic Results with the Pituitary Growth Hormone" Discussed by Drs Roy G Hoskins Boston Murry B Gordon, Brooklyn and Robert L Schaefer Detroit

Dr John Aikman Rochester N Y, read a paper on "The Problem of Accidental Poisoning in Childhood" Discussed by Drs S W Clausen, Rochester N Y C W Wyckoff, Cleveland and John Aikman, Rochester N Y

Dr David T Smith Durham, N C read a paper on "Diagnosis and Treatment of Lung Abscess in Children" Discussed by Drs Louis H Clerf, Philadelphia J W Epstein Cleveland, E F Butler, Elmira N Y and David T Smith Durham N C

FRIDAY, JUNE 15—MORNING

The following officers were elected chairman, Dr A Grieme Mitchell, Cincinnati vice chairman, Dr Walter B Stewart, Atlantic City, N J, secretary, Dr Ralph M Tyson, Philadelphia, delegates, Dr Isaac A Abt, Chicago, alternate, Dr A Grieme Mitchell, Cincinnati, Executive Committee, Drs A Grieme Mitchell Cincinnati Alfred A Walker, Birmingham, Ala, Frederick W Schlutz, Chicago representative on Scientific Exhibit, Dr F Thomas Mitchell, Memphis, Tenn

The following report was presented by the Committee on Scientific Exhibit

This committee wishes first to thank those gentlemen who have so generously devoted their energy and their time to the section exhibit this year This committee regrets that the Committee on Scientific Exhibit of the Board of Trustees had to refuse some requests for space because of the large number of applications received from the Association as a whole

Arrangements have been made to request the committee from the Board of Trustees to consider all the applications from a certain section in one group, which will we hope, insure a more even distribution of space between the sections cooperating in the future

For next year certain innovations are to be added to the exhibit of the Section on Pediatrics and the continued cooperation of the gentlemen in the section is asked

Respectfully submitted

F THOMAS MITCHELL  
W C FARGO  
ABRAHAM LEVINSON

Dr Frank C Neff Kansas City, Mo presented the following report on behalf of the Jacobi Fund Committee

The Jacobi Fund has been in existence and functioning for the ten years just completed During this time the friends of the Section on Pediatrics have contributed sufficient not only for current expenses but to permit a trust fund to be established

It seems to be the consensus of the members of the present committee that the attempt be made to secure only those speakers as guests who have a ready command of English and can be readily understood by an American audience, furthermore, that in most instances a smaller honorarium should be given to the foreign guest

During the coming year it is expected that a small marble tablet or bench will be erected at Lake George near the site of Jacobus' former residence as a memorial to him

The appended treasurer's report lists the activities and expenses of the fund for the past year There has just been completed also a ten-year audit of the committee's books This has been in the hands of the committee members and a copy of it given to the secretary of the section for his records

The following is the Treasurer's report on the Jacobi Fund

Total balance on hand June 1 1934	\$6 267 82
Receipts	
123 Subscriptions	\$627 64
Interest at Traders Gate City National Savings account on which occasional checks are written	11 17

One copy of Transactions not yet paid for

On motion regularly made and seconded the report of the Jacobi Fund Committee was adopted

Dr Isaac A Abt, Chicago, delegate, read the following resolution, presented by the board of directors to the Philadelphia Pediatric Society and adopted by the Philadelphia Pediatric Society at the monthly meeting held Tuesday, Jan 17, 1933

WHEREAS Therapeutics in diseases of infants and children constitutes an important and much neglected phase of pediatric practice and

WHEREAS Those remedial agents prescribed by the profession, official in the United States Pharmacopeia X and National Formulary V are employed extensively in treating disease in infants and children and

WHEREAS The acceptance of new drugs and the deletion of remedies at present official in the Pharmacopeia and National Formulary concerns pediatricians as well as the general practitioner who treats infants and children and

WHEREAS There is a strong tendency to undermine official remedies including those of pediatric importance and therapeutic usefulness by proprietary remedies through clever advertising exploitation and salesmanship therefore be it

Resolved That the Philadelphia Pediatric Society take the initiative in urging the American Academy of Pediatrics the American Pediatric Society and the pediatric section of the American Medical Association through its proper channels to suggest to the officers of the Pharmacopoeial Convention 1930 and to the officers of the National Formulary Convention of 1930 the appointment of a representative group of pediatricians whose function shall be to suggest and advise those remedial agents (drugs and preparations of pediatric importance and therapeutic necessity) to be deleted retained and added to both the Pharmacopeia and the National Formulary who will cooperate with all present committees of the Pharmacopeia and the National Formulary in furthering the work for revision be it further

Resolved That the suggestion of average doses for the periods of infancy and of preschool and school ages be included in both texts as has been carried out previously with Pharmacopoeial and National Formulary remedies in adults and that application be filed with the Committee of Credentials of the Pharmacopoeial Convention and the National Formulary for a permanent seat as delegates to the Convention for 1940

On motion regularly made and seconded, the resolution was adopted

Dr Alexis F Hartman, St Louis, read a paper on "Theory and Practice of Parenteral Fluid Administration" Discussed by Drs Arthur G Helmick, Columbus, Ohio, J C Ray, Louisville, Ky, and Alexis F Hartman St Louis

Dr H H Donnally, Washington, D C read a paper on "A Study of Vaccination in Five Hundred New-Born Infants" Discussed by Drs J A Doull, Cleveland, Frank P Gengenbach, Denver J P Leake Washington, D C, and H H Donnally, Washington, D C

Dr J M Frawley, Fresno Calif read a paper on "The Immunization of School Children Against Whooping Cough" Discussed by Drs Louis W Sauer, Evanston, Ill, H F Helmholz, Rochester, Minn Reuben L Kahn, Ann Arbor, Mich, Jay I Durand, Seattle, J Victor Greenebaum, Cincinnati, and J M Frawley, Fresno, Calif

Drs James E Bowman and P F Lucchesi, Philadelphia, presented a paper on "Antitoxin vs No Antitoxin in Scarlet Fever"

Drs Archibald L Hoyne and John Hays Bailey Chicago, presented a paper on "The Secondary Case of Scarlet Fever"

These two papers were discussed by Drs John A Toomey, Cleveland J E Gordon, Detroit, P F Lucchesi Philadelphia, and Archibald L Hoyne Chicago

## SECTION ON PHARMACOLOGY AND THERAPEUTICS

WEDNESDAY, JUNE 13—MORNING

The meeting was called to order at 9 10 by the chairman, Dr John H Musser New Orleans

Drs Harry L Arnold, Honolulu H I William S Middleton, Madison Wis and K K Chen Indianapolis, presented a paper on 'Clinical Experiences with Thevetin a Cardiac Glucoside' Discussed by Drs R Wesley Scott Cleveland Charles N Hensel, St Paul K K Chen, Indianapolis Norman M Keith, Rochester, Minn, and William S Middleton, Madison

Drs Nelson W Barker George E Brown and Grace M Roth Rochester Minn presented a paper on 'Effect of Tissue Extracts on Muscle Pains of Ischemic Origin (Intermittent Claudication)' Discussed by Drs E V Allen, Rochester, Minn Wallace S Duncan, Cleveland Harold M Rabinowitz Brooklyn Benjamin Jablons, New York Joseph B Wolffe Philadelphia and Nelson W Barker, Rochester

Drs Alvan L Barach and Robert L Levy, New York, presented a paper on "Oxygen in the Treatment of Acute Coronary Occlusion" Discussed by Drs Walter M Boothby, Rochester Minn, A Carlton Ernstene, Cleveland, Ford K Hick Chicago, Louis F Bishop Jr, New York, Martin Friedrich, Brooklyn, Alvan L Barach, New York, and Robert L Levy, New York

Drs James B Collip and E M Anderson, Montreal, Canada, presented a paper on "Studies on the Thyrotropic Hormone of the Anterior Pituitary"

Drs James H Means and Jacob Lerman, Boston, presented a paper on "Action of Iodine in Thyrotoxicosis, with Special Reference to Refractoriness"

Drs W O Thompson and S G Taylor III, Chicago, S B Nadler, New Orleans, P K Thompson and L F N Dicke Chicago, presented a paper on "Pharmacology of the Thyroid in Man"

These three papers were discussed by Drs George W Crile Cleveland, E C Kendall, Rochester, Minn, Herrmann L Blumgart, Boston, A C Ivy, Chicago, George M Curtis Columbus, Ohio, Harold T Hyman, New York, E P McCullagh, Cleveland, Walter M Boothby, Rochester, Minn, James B Collip Montreal, James H Means, Boston, and W O Thompson, Chicago

THURSDAY, JUNE 14—MORNING

Dr Charles A Doan and Lowell A Erf, Columbus, Ohio, presented a paper on "The Differential Diagnosis and Therapeutic Rationale of Leukopenic States" Discussed by Drs Roy R Kracke, Emory University, Ga, Henry N Harkins, Chicago, William Dameshek, Boston William H Gordon, Detroit, and Charles A Doan, Columbus

Dr Frank H Bethell, Ann Arbor, Mich, read a paper on "The Diagnosis and Treatment of the Iron Deficiency Anemias"

Drs William Dameshek and William B Castle, Boston presented a paper on "An Assay of Various Extracts of Liver for Parenteral Use"

These two papers were discussed by Drs Cyrus C Sturgis Ann Arbor, W P Murphy, Boston, Adolph Sachs, Omaha C W Edmunds, Ann Arbor, Mich, Frank H Bethell, Ann Arbor, and William Dameshek, Boston

Dr John H Musser, New Orleans, read the chairman's address, entitled 'The Pharmacologist and the Therapeutist'

Drs Gerald S Shibley and Tom D Spies, Cleveland, presented a paper on "The Effect of Vitamin A on the Common Cold"

Dr Harold S Diehl, Minneapolis, read a paper on "The Treatment of the Common Cold"

These two papers were discussed by Drs K K Chen, Indianapolis, Tom D Spies, Cleveland, William J Kerr, San Francisco, Russell L Haden, Cleveland, Gerald S Shibley, Cleveland, and Harold S Diehl, Minneapolis

FRIDAY, JUNE 15—MORNING

The following officers were elected chairman, Dr C H Greene, New York, vice chairman Dr Chauncey D Leake San Francisco secretary, Dr Russell L Haden Cleveland, delegate, Dr Cary Eggleston, New York, alternate, Dr Robert L Levy, New York, executive committee, Dr E M K Geiling Baltimore Dr John H Musser, New Orleans, and Dr C H Greene, New York

Drs C Glenville Giddings Jr and Everett L Bishop Atlanta Ga presented a paper on 'A Study of the Effect of Caffeine on Rabbits' Discussed by Drs C W Edmunds, Ann Arbor, Mich and Roy R Kracke, Emory University, Ga

Dr Elmer L Sevringhaus, Madison, Wis presented a paper on "The Relief of Menopause Symptoms by Follicular Hormone Therapy" Discussed by Drs Emil Novak, Baltimore, J P Pratt, Detroit, E P McCullagh Cleveland J I Hoffbauer, Cincinnati and Elmer L Sevringhaus, Madison, Wis

Drs C W Edmunds and Nathan B Eddy, Ann Arbor Mich presented a paper on 'Studies of Morphine Substitutes'

Dr C K Himmelsbach Fort Leavenworth Kan, read a paper on 'The Addiction Liability of Codeine'

Dr C Malone Stroud St Louis read a paper on 'The Use of Dilaudid in the Pain of Cancer'

These three papers were discussed by Drs Torald Sollmann Cleveland Norman A David Morgantown, W Va, Harold

S Diehl, Minneapolis, Nathan B Eddy, Ann Arbor, Mich, C K Himmelsbach, Fort Lavenworth, Kan, and C Malone Stroud, St Louis

Dr Eugene de Sztitsch, Chicago, read a paper on "The Role of Hypercalcemia in the Presence of the Tuberculin Reaction in Experimental Tuberculosis" Discussed by Drs Harry J Corper, Denver, David J Smith, Durham, N C, Torald Sollmann, Cleveland, and Eugene de Sztitsch, Chicago

Drs Harold Thomas Hyman and Arthur S W Touroff, New York, presented a paper on "Further Observations on the Therapeutics of the Intravenous Drip" Discussed by Drs T G Orr, Kansas City, Mo Paul Titus, Pittsburgh, Robert Kapsinow, Lafayette, La, and Harold Thomas Hyman, New York

## SECTION ON PATHOLOGY AND PHYSIOLOGY

WEDNESDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2 10 by the chairman, Dr William Carpenter MacCarty, Rochester, Minn

On motion regularly made and seconded, it was voted to nominate the following for Associate Fellowship Maurice L Cohn, Denver, and Moyer S Fleisher, St Louis

Dr Claude Moore, Washington, D C, read a paper on "Giant Cell Tumors Their Pathology and Possible Etiology" Discussed by Drs Eugene R Whitmore, Washington, D C, Joseph C Bloodgood, Baltimore E H Skinner, Kansas City, Mo, William Carpenter MacCarty, Rochester, Minn, and Claude Moore, Washington, D C

Dr Alvin G Foord, Pasadena, Calif, read a paper on "Hyperproteinemia, Autohemo-Agglutination and Abnormal Bleeding in Multiple Myeloma Observations in Three Cases" Discussed by Drs Russell L Haden, Cleveland, and Alvin G Foord, Pasadena Calif

Dr E B Krumbhaar, Philadelphia, read a paper entitled "Is Hodgkin's Disease a Neoplasm or Due to Infection?" Discussed by Drs Oscar B Hunter, Washington, D C, William Carpenter MacCarty, Rochester, Minn, and E B Krumbhaar, Philadelphia

Dr William Carpenter MacCarty, Rochester, Minn, read the chairman's address, entitled "The Cancer Problem Today"

Dr Max Cutler, Chicago, read a paper on "The Problems of Radiosensitivity of Tumors" Discussed by Drs Joseph C Bloodgood, Baltimore, J Shelton Horsley, Richmond, Va, E B Krumbhaar, Philadelphia, and Max Cutler, Chicago

Dr Eugene R Whitmore, Washington, D C, read a paper on "Hypernephroid Tumors of the Kidney" Discussed by Drs Lester Neuman, Washington, D C R M LeComte, Washington, D C, Russell Ferguson, New York, William Carpenter MacCarty, Rochester, Minn, and Eugene R Whitmore, Washington, D C

Dr Philip B Matz, Washington, D C, read a paper on "Heart Disease in Veterans A Survey of Six Hundred and Eleven Autopsies" Discussed by Dr Wallace M Yater, Washington, D C

THURSDAY, JUNE 14—AFTERNOON

Drs H J Corper, A P Damerow and Maurice L Cohn, Denver, presented a paper on "Specific Viable Vaccines in Tuberculosis" Discussed by Drs Francis M Pottenger, Monrovia, Calif, and H J Corper, Denver

Dr Maxwell Finland, Boston, read a paper on "The Significance of Mixed Infections in Pneumonia" Discussed by Drs W D Sutliff, Chicago, and Maxwell Finland, Boston

Dr Reuben L Kahn, Ann Arbor Mich read a paper on "Tissue Reactions in Immunity Some Clinical Implications" Discussed by Drs Walter M Simpson, Dayton, Ohio, Israel Davidson, Chicago, Francis M Pottenger, Monrovia, Calif, and Reuben L Kahn, Ann Arbor, Mich

Dr Edwin E Osgood, Portland Ore, read a paper on "Normal Hematologic Standards" Discussed by Drs Russell L Haden, Cleveland, M B Lyon, South Bend, Ind, and Edwin E Osgood, Portland, Ore

Dr B K Wiseman, Columbus, Ohio read a paper on "The Origin of the White Blood Cells" Discussed by Dr Charles A Doan, Columbus, Ohio

Dr L W Diggs, Memphis, Tenn, read a paper on "The Splen in Sickle Cell Anemia" Discussed by Drs John Corrigan, Boston, Charles A Doan, Columbus, Ohio, and L W Diggs, Memphis, Tenn

Dr Leon Schiff, Cincinnati, read a paper on "A Study of One Hundred Cases of Jaundice (With Particular Reference to Icterus Ictericus)" Discussed by Drs F C Mann, Rochester, Minn, and Harry Shry, Philadelphia

FRIDAY, JUNE 15—AFTERNOON

The following officers were elected chairman, Dr Elias P Lyon, Minneapolis, vice chairman, Dr Henry C Swamy, Chicago, secretary, Dr J J Moore, Chicago, delegate, Dr D J Davis, Chicago, alternate, Dr J J Moore, Chicago, Executive Committee, Drs Elias P Lyon, Minneapolis, William Carpenter MacCarty, Rochester, Minn, and Clyde Brooks, New Orleans

The following motion was adopted

That a committee be appointed by the Section on Pathology and Physiology to consider the formation of a board of examiners in pathology and clinical pathology for the purpose of certifying physicians in these respective branches of medicine such committee to meet with similar committees from the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists

Dr Allan Winter Rowe, Boston, read a paper on "The Metabolism of Levulose VI The Influence of Gonadal Function on Tolerance" Discussed by Dr Henry J John, Cleveland

Drs Edward J Stieglitz and Alva A Knight Chicago, presented a paper on "Sodium Ferrocyanide as a Clinical Test of Glomerular Efficiency" Discussed by Dr Edward J Stieglitz, Chicago

Dr Russell S Ferguson, New York, read a paper entitled "Preliminary Note on the Isolation of Aquamedin and Its Specific Effect in Diabetes Insipidus" Discussed by Drs Howard T Karsner, Cleveland, and Russell S Ferguson, New York

Dr William Bierman, New York, read a paper on "Some Changes Occurring During Hyperpyrexia Induced by Physical Means" No discussion

Dr Nicholas M Alter, Jersey City, N J, read a paper on "The Functions of a Full Time Pathologist" Discussed by Drs William Carpenter MacCarty, Rochester, Minn, and Nicholas M Alter, Jersey City, N J

Dr Margaret Warwick, Buffalo, read a paper on "Obtaining Permission for Autopsies" Discussed by Drs R S Rosedale, Buffalo, and William Carpenter MacCarty, Rochester Minn

## SECTION ON NERVOUS AND MENTAL DISEASES

WEDNESDAY, JUNE 13—MORNING

The meeting was called to order at 9 10 by the chairman, Dr Henry W Woltman, Rochester, Minn

Dr I S Wechsler, New York, read a paper on "Trauma and the Nervous System, with Special Reference to Head Injuries and a Classification of Posttraumatic Syndromes (Analysis of One Hundred Cases)" Discussed by Drs N W Winkelman, Philadelphia, George B Hassin, Chicago, Temple Fay Philadelphia, J L Fetterman, Cleveland, George W Hall, Chicago, Walter Freeman, Washington, D C, Max H Weinberg, Pittsburgh, C C Nash Dallas, Texas, E E Mayer, Pittsburgh, and I S Wechsler, New York

Drs N W Winkelman, Philadelphia, and John L Eekel, Buffalo, presented a paper on "Spastic Paraplegia Cases Illustrating the Common Etiologic Factors" Discussed by Drs I S Wechsler, New York, and N W Winkelman, Philadelphia

Drs Edward H Rynearson and Frederick P Moersch, Rochester, Minn, presented a paper on "The Neurologic Manifestations of Hyperinsulinism and Other Hypoglycemic States" Discussed by Drs I S Wechsler, New York, George W Hall, Chicago Harlow Brooks, New York, Tom B Throckmorton, Des Moines Iowa, and Edward H Rynearson, Rochester, Minn

Drs A E Bennett and J Jay Keegan, Omaha, presented a paper on "The Diagnosis of Cerebral Neoplasm in the Absence of Generalized Intracranial Pressure Phenomena" Discussed by Drs Alfred W Adson Rochester Minn, Lloyd H Ziegler, Albany, N Y, George W Hall, Chicago, Temple Fay, Phila-

delphia, W James Gardner, Cleveland, Albert S Crawford, Detroit, Walter D Abbott, Des Moines, Iowa, and A E Bennett, Omaha

Dr William P Van Wagenen, Rochester, N Y, read a paper on "The Diagnosis and Surgical Treatment of Chordoma of the Basilar Plate" Discussed by Drs John L Eckel, Buffalo, W James Gardner, Cleveland, and Alfred W Adson, Rochester, Minn

Dr H C Voris, Rochester, Minn, read a paper on 'Frontal Lobe Tumors Clinical Observations in a Verified Series' Discussed by Drs Alfred W Adson, Rochester Minn, F J Gerty, Chicago, Lloyd H Ziegler, Albany, N Y, Adrien H P E Verbrugghen, Chicago, and H C Voris, Rochester, Minn

Dr Walter Freeman, chairman, gave the report of the committee appointed by the section to meet with similar committees of the American Psychiatric Association and American Neurological Association to consider the formation of a Board of Examiners in Psychiatry and Neurology, the other members of the committee being Drs J Allen Jackson, Lloyd H Ziegler, George W Hall and Edwin G Zabriskie It was moved by Dr E E Mayer of Pittsburgh, seconded by Dr John L Eckel of Buffalo and carried, that the report of the committee be adopted as read

#### THURSDAY, JUNE 14—MORNING

Dr Henry W Woltman, Rochester, Minn read the chairman's address, entitled "Enduring Achievements of Sir Charles Bell"

The following papers were read as a symposium on "The Functions of the Cerebral Cortex"

##### "Frontal Lobes"

Dr Paul C Bucy, Chicago "The Relation of Cerebral Architecture of the Frontal Lobes of Primates to Functional Activity"

Drs J F Fulton, New Haven, Conn, and Henry R Viets, Boston "The Syndromes of the Motor and Premotor Areas"

Dr C F Jacobsen, New Haven, Conn "Functions of the Frontal Association Areas in Primates"

These three papers were discussed by Drs I S Wechsler, New York, John L Eckel, Buffalo, James B Ayer Boston, Walter Freeman, Washington, D C, Theodore Diller, Pittsburgh, A L Skoog, Kansas City, Mo Paul C Bucy, Chicago, Henry R Viets, Boston C F Jacobsen, New Haven, Conn, and J F Fulton, New Haven Conn

##### "Autonomic Representation in the Cortex"

Dr Margaret A Kennard, New Haven, Conn "Vasomotor Disturbances Resulting from Cortical Lesions"

Dr James W Watts, Philadelphia "The Influence of the Cortex on Gastro-Intestinal Movements"

These two papers were discussed by Drs John Paul Quigley, Cleveland Paul C Bucy, Chicago Thomas J Heldt, Detroit, Margaret A Kennard New Haven, Conn, and James W Watts, Philadelphia

##### "Occipital Lobes"

Dr Stephen Poljak, Chicago "Structure of the Retina and Its Cerebral Representation in Primates and in Man"

Dr Donald Marquis, New Haven Conn "A Phylogenetic Interpretation of the Functions of the Visual Cortex"

These two papers were discussed by Drs Franklin Jelsma, Louisville Ky Albert T Steegmann, Cleveland, Edmond E Blaauw, Buffalo Stephen Poljak, Chicago, and Donald Marquis New Haven, Conn

#### FRIDAY, JUNE 15—MORNING

The following officers were elected chairman, Dr H Douglas Singer, Chicago vice chairman Dr George S Johnson San Francisco secretary, Dr Henry R Viets Boston delegate, Dr Tom B Throckmorton, Des Moines, Iowa alternate, Dr Edward Delehanty Denver Executive Committee, Dr George B Hassin Chicago Dr Henry W Woltman, Rochester, Minn Dr H Douglas Singer Chicago

Dr Frederick S Wetherell, Syracuse N Y, read a paper on 'Multiple Sclerosis Cervicodorsal Sympathectomy as a Relief Measure' Discussed by Drs Noble R Chambers, Syracuse N Y George B Hassin Chicago Temple Fay, Philadelphia Henry R Viets, Boston W James Gardner, Cleveland Albert S Crawford Detroit Henry W Woltman, Rochester Minn and Frederick S Wetherell Syracuse N Y

Dr William Sharpe, New York, read a paper on 'Diagnostic and Therapeutic Lumbar Punctures of Spinal Drainage in Selected Traumatic and Allied Lesions of the Central Nervous System' Discussed by Drs Temple Fay, Philadelphia, Albert S Crawford, Detroit, Ned R Smith, Tulsa, Okla, Paul C Bucy, Chicago, Samuel D Swope, El Paso, Texas, A L Skoog, Kansas City, Mo, Adrien Verbrugghen, Chicago, and William Sharpe, New York

Drs Carlo J Tripoli, William M McCord and Howard H Beard, New Orleans, presented a paper on "Muscular Dystrophy, Muscular Atrophy and Myasthenia Gravis A Review of Clinical and Biochemical Studies of the Effects of Amino Acid" Discussed by Drs Walter M Boothby, Rochester, Minn, K K Chen, Indianapolis, Henry A Monat, Dayton, Ohio Clarence O Cheney, New York, Henry W Woltman, Rochester, Minn, Howard H Beard, New Orleans, and Carlo J Tripoli, New Orleans

Drs Siegfried E Katz and Carney Landis, New York, presented a paper on 'Physiologic and Psychologic Phenomena Produced by a Prolonged Vigil' Discussed by Drs Clarence O Cheney New York, Lloyd H Ziegler, Albany, N Y, and Siegfried E Katz, New York

Dr Lauren H Smith, Philadelphia, read a paper on 'The Treatment of Psychoneuroses in General Practice' Discussed by Drs Alan D Finlayson, Cleveland, Harold Cohn, Cleveland Lloyd H Ziegler, Albany, N Y, T Earl Moore, Miami, Fla and Lauren H Smith, Philadelphia

Drs Charles F Read and John F Nerancy, Elgin, Ill, presented a paper on "Modern State Hospital Treatment of Mental Diseases" Discussed by Drs Clarence O Cheney, New York, George B Hassin, Chicago, H J Gahagan, Chicago, and Charles F Read, Elgin, Ill

#### SECTION ON DERMATOLOGY AND SYPHILOLOGY

##### WEDNESDAY, JUNE 13—MORNING

The meeting was called to order at 9 20 by the chairman Dr C Guy Lane Boston

Dr Harold N Cole, Cleveland read the following resolution which had been adopted at the meeting of the American Dermatological Association

That a committee of five be appointed by the President of the American Dermatological Association to act as the representatives of the association at the international congress to be held at Budapest in 1935 and that it be the sense of the association that a committee of the same number shall be appointed from the Section on Dermatology and Syphilology of the American Medical Association the two to form a joint committee to act for the American members of the congress the committee to remain in force for two years or more if necessary until the meeting actually transpires

Dr Cole moved that the chairman be empowered to appoint such a committee from the Section on Dermatology and Syphilology The motion was seconded by Dr George M MacKee New York and carried

Dr C Guy Lane, Boston, read the chairman's address, entitled "Postgraduate Dermatologic Training and Its Relationship to Certification of Specialists in Dermatology"

Drs Erwin P Zeisler and Marcus R Caro Chicago, presented a paper on "Necrobiosis Lipoidica Diabetorum" Discussed by Drs Udo J Wile Ann Arbor, Mich Fred D Weidman Philadelphia, Jeffrey C Michael, Houston, Texas, and Erwin P Zeisler Chicago

Dr Frank Stiles Jr Ann Arbor, Mich, read a paper on 'Clinical Mutations in Lymphoblastomas' Discussed by Drs Harther L Keim Detroit George M MacKee New York Marion B Sulzberger, New York William H Guy, Pittsburgh Fred D Weidman, Philadelphia, and Frank Stiles Jr, Ann Arbor, Mich

Dr George M Lewis, New York, read a paper entitled 'Is Spiegler-Fendt Sarcoid a Clinical or Histologic Entity?' Discussed by Drs Robert L Gilman Philadelphia, George M MacKee New York John Rauschkolb, Columbus, Ohio and George M Lewis, New York

Dr Ashton L Welsh Rochester, Minn read a paper on 'Studies on the Specificity of a Streptococcus Isolated from Cases of Pemphigus Preliminary Report' Discussed by Dr Louis A Brunsting Rochester, Minn Theodore Cornbleet, Chicago, and Ashton L Welsh Rochester Minn

Dr James Herbert Mitchell, Chicago, read a paper on "Streptococcal Infections Simulating Ringworm of the Hands and Feet" Discussed by Drs George C Andrews, New York, Frank P Zeisler, Chicago Marion B Sulzberger, New York John G Downing Boston, and James Herbert Mitchell Chicago

Drs George M MacKee and Anthony C Cipollaro New York presented a paper on "The Roentgen Unit in Dermatology" Discussed by Drs Otto Glasser Cleveland, Earl W Netherton, Cleveland, George C Andrews, New York, C Guy Lane Boston C F Ichimura San Antonio Texas, Lester Hollander, Pittsburgh George M MacKee New York, and Anthony C Cipollaro, New York

Drs Fred D Weidman and Jacques P Guequierre Philadelphia presented a paper on "The Role of High Frequency Currents in the Performance and Histologic Interpretation of Biopsy Samples" Discussed by Drs George M MacKee, New York Max S Wien Chicago Fred D Weidman, Philadelphia, and Jacques P Guequierre, Philadelphia

#### THURSDAY, JUNE 14—MORNING

Dr Fred D Weidman reported for the Scientific Exhibit Committee that the section had a balance of \$154 for use over a period of four or five years and that the collecting of contributions for the exhibit would be forbidden in the future, but that the American Medical Association had made an allotment to the fund Dr Weidman especially asked members who are heads of departments to call to the attention of the committee work representing scientific advance that might be available for exhibits

It was voted, on motion of Dr Howard Morrow San Francisco, seconded by Dr Francis E Seneer Chicago that the report of the auditing committee on the finances of the section referable to the Scientific Exhibit be accepted and filed

The chairman appointed the following Committee on the International Congress Drs Harold N Cole Cleveland John H Stokes, Philadelphia Fred D Weidman, Philadelphia, Paul O Leary, Rochester, Minn, and William H Guy Pittsburgh

Drs Theodore Cornbleet and Morris A Kaplan, Chicago presented a paper on "Urinary Proteose in Eczema" Discussed by Drs Robert E Barney, Cleveland Frank J Eichenlaub, Washington D C Max E Obermayer, Chicago Warren T Vaughan, Richmond, Va, and Theodore Cornbleet, Chicago

Dr Arthur F Coca, New York, read a paper on "The Present Status of the Specific Diagnosis and Treatment of the Allergic Diseases of the Skin"

Drs Louis A Brunsting and C R Anderson, Rochester, Minn, presented a paper on "Ragweed Dermatitis"

Drs Samuel Ayres Jr and Nelson Paul Anderson Los Angeles, presented a paper on "Some Observations on Light Sensitive Dermatoses"

Dr Cleveland J White Chicago read a paper on "Acne-Like Dermatoses Due to Food Allergy"

These four papers were discussed by Drs Marion B Sulzberger New York, Jeffrey C Michael Houston Texas James R Driver Cleveland Albert H Rowe Oakland Calif C Malone Stroud St Louis George L Waldbott, Detroit A B Loveman, Louisville, Ky, Leon Unger Chicago, Joseph Muller, Worcester Mass, Samuel M Peck New York Howard Fox New York Armand E Cohen Louisville Ky Arthur F Coca New York Louis A Brunsting Rochester Minn Nelson Paul Anderson Los Angeles and Cleveland J White Chicago

Dr Richard L Sutton Jr Kansas City, Mo, read a paper on "Early Cutaneous Carcinoma" Discussed by Drs E W Netherton, Cleveland Harold N Cole Cleveland, Jeffrey C Michael Houston, Texas and Richard L Sutton Jr, Kansas City, Mo

Drs Herman Beerman George V Kulchar Donald M Pillsbury and John H Stokes Philadelphia presented a paper on "Dioxyanthranol 1-8 as a Substitute for Chrysarobin" Discussed by Drs Robert C Jamieson Detroit Max E Obermayer Chicago Fred D Weidman Philadelphia Louis A Brunsting Rochester, Minn, George W Raiziss Philadelphia and Herman Beerman Philadelphia

Dr Howard Fox, New York, read a paper on "Verruca Peruviana as Observed in Peru" Discussed by Drs Harold N Cole, Cleveland, and Howard Fox, New York

#### FRIDAY, JUNE 15—MORNING

The following officers were elected chairman, Dr Jeffrey C Michael, Houston, Texas, vice chairman, Dr James R Driver, Cleveland, secretary, Dr Harry R Foerster, Milwaukee, delegate, Dr Clyde L Cummer, Cleveland, alternate, Dr Robert C Jamieson Detroit

Drs Samuel M Peck and Harold A Abel, New York, presented a paper on "Clinical and Experimental Experiences with Snake Venom" Discussed by Drs John A Gammel, Cleveland, Marion B Sulzberger New York, Fred D Weidman, Philadelphia, and Samuel M Peck, New York

Drs Maurice J Strauss and Marion E Howard, New Haven, Conn, presented a paper on "The Frei Test for Lymphogranuloma Inguinale Recovery of the Antigen from a Pustular Reaction" Discussed by Drs Max S Wien, Chicago, Walter S Grant, Chicago, John E Dalton, Indianapolis Elmore B Tauber, Cincinnati, and Maurice J Strauss, New Haven, Conn

Dr Leslie P Barker, New York read a paper on "Organic Luetin Its Value in Diagnosis and Treatment of Syphilis A Study of Five Hundred Cases"

Dr Arthur G Schoch Dallas, Texas, read a paper on "Arsphenamine Dermatitis Attempted Sensitization to Neoarsphenamine and Further Observations on the Patch Test"

These two papers were discussed by Drs John E Rauschkolb, Cleveland Harry M Robinson, Baltimore, Marion B Sulzberger, New York, John V Ambler Denver, George W Raiziss, Phil D, Philadelphia, Drs Elmore B Tauber, Cincinnati, Maurice J Strauss, New Haven, Conn, Louis A Brunsting Rochester, Minn Leslie P Barker, New York, and Arthur G Schoch, Dallas, Texas

Drs Norman N Epstein and Maurice Cohen San Francisco, presented a paper on "The Effects of Hyperpyrexia Produced by Radiant Heat in Early Syphilis Description of a Simple Method of Producing Hyperpyrexia"

Drs Stanley O Chambers and George F Koetter, Los Angeles, presented a paper on "Bismarsen in the Treatment of Congenital Syphilis"

Dr Louis Chargin New York, read a paper on "The Application of the Intravenous Drip Method of Chemotherapy as Illustrated by Massive Doses of Neoarsphenamine in the Treatment of Early Syphilis"

These three papers were discussed by Drs Howard J Parkhurst Toledo, Ohio, Herman Beerman, Philadelphia, Clyde L Cummer, Cleveland Walter M Simpson, Dayton, Ohio, Harold N Cole, Cleveland, Harry M Robinson, Baltimore, Norman N Epstein, San Francisco Stanley O Chambers, Los Angeles, and Louis Chargin, New York

#### SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

##### WEDNESDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2 05 by the chairman, Dr Wilson G Smilie Boston

On motion made by Dr William A Sawyer Rochester N Y seconded by Dr J E Gordon, Detroit, it was voted unanimously that Dr James G McAlpine of Montgomery, Ala, be admitted to Associate Fellowship

The chairman appointed as the nominating committee Drs F D Stricker Portland, Ore J E Gordon, Detroit, and A J Chesley, St Paul

The following papers were read as a symposium on "Lead Poisoning"

Dr Wilson G Smilie Boston Chairman's address

Dr A J Lanza, New York Epidemiology of Lead Poisoning

Dr Joseph C Aub Boston Chemistry of Lead in the Body

Dr Robert A Kehoe, Cincinnati "Normal Absorption and Excretion of Lead"

Dr R R Jones, Washington, D C "Symptoms in Early Stages of Lead Poisoning"

Dr Elston L Belknap, Milwaukee "Control of Lead Poisoning in the Worker"

Dr Irving Gray, Brooklyn "Recent Progress in the Treatment of Plumbism"

These seven papers were discussed by Drs George H Gehrmann, Wilmington, Del, Paul A Davis, Akron, Ohio, Millard Knowlton, Hartford, Conn, Elbridge J Best, San Francisco, A J Lanza, New York, Robert A Kehoe, Cincinnati, R R Jones, Washington, D C, Elston L Belknap, Milwaukee, Irving Gray, Brooklyn, and Joseph C Aub, Boston

#### THURSDAY, JUNE 14—AFTERNOON

Dr Leroy E Parkins, Boston, read a paper on "The Relation of Postgraduate Medical Instruction to Public Health" Discussed by Drs J E Gordon, Detroit, Emery R Hayhurst, Columbus, Ohio, Dwight O'Hara, Boston, Benjamin Goldberg, Chicago, and Leroy E Parkins, Boston

Drs John W Miller, Washington, D C, William P Yant, Pittsburgh, and R R Sayers, Washington, D C, presented a paper on "The Response of Peritoneal Tissue to Dusts Introduced as Foreign Bodies" Discussed by Drs A J Lanza, New York, William D McNally, Chicago, Emery R Hayhurst, Columbus, Ohio, and John W Miller, Washington, D C.

Drs Alberto Hurtado, W W Fray, N L Kaltreider and William S McCann, Rochester, N Y, presented a paper on "The Estimation of Functional Disability in the Pulmonary Fibroses" Discussed by Drs James L Dubrow, Des Moines, Iowa, William D McNally, Chicago, Benjamin Goldberg, Chicago, William S McCann, Rochester, N Y, and Emery R Hayhurst, Columbus, Ohio

Dr C O Sappington, Chicago, read a paper on "The Control of Occupational Diseases by Laboratory Methods" Discussed by Dr Albert S Gray, Hartford, Conn

Dr Paul A Davis, Akron, Ohio, read a paper on "Carbon Tetrachloride as an Industrial Hazard" Discussed by Drs Carey P McCord, Cincinnati, Z T Wirtschafter, Cleveland, Emery R Hayhurst, Columbus, Ohio, William D McNally, Chicago, Wilson G Smilie, Boston, and Paul A Davis, Akron, Ohio

Dr F D Stricker, Portland, Ore, read a paper on "The Effects of Consolidation of State Health, Welfare and Licensure Functions to Preventive Medicine" Discussed by Drs John A Ferrell, New York, George H Coombs, Augusta, Maine, and F D Stricker, Portland, Ore

Dr H Jackson Davis, Albany, N Y, read a paper on "Coordination of Medical Relief, Federal, State and Local, Based on More Than Two Years' Experience in New York State" Discussed by Dr A J Chesley, St Paul

#### FRIDAY, JUNE 15—AFTERNOON

The following officers were elected chairman, Dr Robert H Riley, Baltimore, vice chairman, Harry L Rockwood, Cleveland, secretary, R R Sayers, Washington, D C, delegate, Stanley H Osborn, Hartford, Conn

The chairman announced the appointment of Dr A J Chesley, St Paul, as a member of the Executive Committee in the absence of Dr J N Baker, Montgomery, Ala

The following papers were presented on the topic "Epidemic Encephalitis"

Dr Josephine B Neal, New York "The Encephalitis Problem"

Drs J P Leake, Washington, D C, E K Musson, Jefferson City, Mo, and H D Chope, St Louis "Epidemiology"

Drs Howard Anderson McCordock, William D Collier and Samuel H Gray, St Louis "Pathology"

Drs Ralph S Muckenfuss, St Louis, Charles Armstrong, Washington, D C and Leslie T Webster, New York "Etiology"

Dr Theodore C Hempelmann, St Louis "Diagnosis"

Dr J W Eschenbrenner, St Louis "Treatment"

Drs Joseph F Bredeck and Paul J Zentay, St Louis "Handling the Epidemic"

These seven papers were discussed by Drs W E Conklin, Paris, Ill, Frank R Finnigan, St Louis, J W Eschenbrenner, St Louis, Ralph S Muckenfuss, St Louis, and Paul J Zentay, St Louis

#### SECTION ON UROLOGY

#### WEDNESDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr Harry Culver, Chicago

The following papers were read as a symposium on "Gonorrhea"

Dr Percy S Pelouze, Philadelphia "Immunologic Aspects of Gonococcal Infections"

Dr Russell D Herrold, Chicago "The Treatment of Gonorrhea Based on Laboratory Observations During the Course of the Disease"

Dr Emily Dunning Barringer, New York "The Treatment of Gonorrhea in Women"

These three papers were discussed by Drs Henry W E Walther, New Orleans, Herbert T Hayes, Houston, Texas, Roy W Mohler, Philadelphia, Augustus Harris, Brooklyn, A L Wolbarst, New York, A G Fleischman, Des Moines, Iowa, Percy S Pelouze, Philadelphia, Russell D Herrold, Chicago, and Emily Dunning Barringer, New York

Drs Robert E Cumming and Robert A Burhans, Detroit, presented a paper on "Experiences with Corbus Ferry Bouillon Filtrate and Other Forms of Intradermal Therapy in the Treatment of Gonorrhea" Discussed by Drs Budd C Corbus, Chicago, and Robert E Cumming, Detroit

Mr Ambrose J King, London, England, read a paper on "The Criteria of Cure of Gonorrhea" Discussed by Drs Miley B Wesson, San Francisco, Joseph A Hyams, New York, John F Hogan, Baltimore, and Mr Ambrose J King, London, England

Dr Joseph F McCarthy, New York, read a paper on "Instrumental Methods of Procedure in the Correction of Prostatic and Vesicular Conditions"

Dr Gershom J Thompson, Rochester, Minn, read a paper on "The Treatment of Chronic Prostatitis by Incision with Electrocautery"

Dr Albert E Goldstein, Baltimore, read a paper on "Indications and Methods in Handling the Surgical Complications Occurring in the Treatment of Gonorrhea"

These three papers were discussed by Drs William N Taylor, Columbus, Ohio, J Sidney Ritter, New York, Elmer Hess, Erie, Pa, Cyril K Church, New York, Joseph F McCarthy, New York, Gershom J Thompson, Rochester, Minn, and Albert E Goldstein, Baltimore

Dr Ralph L Dourmashkin, New York, read a paper on "The Operating Dilatocysto-Urethroscope for Use in the Female Urethra"

#### THURSDAY, JUNE 14—AFTERNOON

Dr Harry Culver, Chicago, read the chairman's address, entitled "The Importance of the Streptococcus in Genito-Urinary Diseases"

In the absence of two members of the Executive Committee, Drs J D Barney and N G Alcock, Chairman Culver appointed Drs H C Bumpus Jr and Alexander Raymond Stevens to serve on the committee

Drs Anson L Clark and Bert F Keltz, Oklahoma City, presented a paper on "A Simplified Treatment of Bacilluria"

Dr Albert M Crance, Geneva, N Y, presented a paper on "The Necessity for the Standardization of the Treatment of Bacilluria"

These two papers were discussed by Drs William P Herbst Jr, Washington, D C, Clifford J Barborka, Chicago, Henry F Helmholz, Rochester, Minn, Anson L Clark, Oklahoma City, and Albert M Crance, Geneva, N Y

Drs Monroe E Greenberger and Leonard P Wershub, New York, and Oscar Auerbach, West New Brighton, S I, N Y, presented a paper on "The Incidence of Renal Tuberculosis in Five Hundred Autopsies for General and Pulmonary Tuberculosis"

Dr Frederick Lieberthal, Chicago, read a paper on "Tuberculous Nephritis"

These two papers were discussed by Drs Roy B Henline, New York, Thomas D Moore, Memphis, Tenn, William Rosenberg, Cleveland, Boris E Greenberg, Boston, Monroe E Greenberger, New York, and Frederick Lieberthal, Chicago.

Drs Stanley R Woodruff, Jersey City, N J, and H C Bumpus Jr, Pasadena, Calif, presented a paper entitled 'Is Nephrectomy Always Indicated Following a Diagnosis of Unilateral Renal Tuberculosis?' Discussed by Drs R M LeComte, Washington, D C, J C Pennington, Nashville, Tenn, Hugh H Young, Baltimore, and H C Bumpus Jr, Pasadena, Calif.

Dr Hugh H Young, Baltimore, read a paper on "Genital Tuberculosis" Discussed by Drs W F Bransch, Rochester, Minn, and C I McDavitt, Cincinnati.

Dr Stanley L Wang, New York, read a paper on 'Quartz Light Therapy in Urogenital Tuberculosis' No discussion.

#### FRIDAY, JUNE 15—AFTERNOON

The following officers were elected chairman, Dr Stanley R Woodruff, Jersey City, N J, vice chairman, Dr Thomas P Shupe, Cleveland, secretary, Dr J H Morrissey, New York, delegate, Dr Henry W E Walther, New Orleans, alternate, Dr Henry L Sanford, Cleveland.

It was voted on motion of Dr Alexander Raymond Stevens, New York, that the executive committee be empowered to appoint three members of the section to the qualification board with power to act. Dr Stevens reported the consensus of the acting executive committee that each year one member of the qualification board committee should retire and one new member be appointed.

The following papers were read as a symposium on "Urolithiasis".

Drs Virgil S Counsellor and James T Priestley, Rochester, Minn, "The Present Conception of Renal Lithiasis" Discussed by Drs Jerome M Lynch, New York, Richard Chute, Boston, and Virgil S Counsellor, Rochester, Minn.

Dr Charles C Higgins, Cleveland, "Urinary Calculi: Experimental and Clinical Studies" Discussed by Dr Vincent J O'Connor, Chicago.

Dr Alexander Raymond Stevens, New York, "Bilateral Urinary Calculi: The Medical and Surgical Handling of Problems Involved" Discussed by Drs John S Lewis Jr, Youngstown, Ohio, and Moses Swick, New York.

Dr Linwood D Keyser, Roanoke, Va, "Recurrent Urolithiasis: Etiologic Factors and Clinical Management" Discussed by Drs George H Ewell, Madison, Wis, Francis P Twinn, New York, and Linwood D Keyser, Roanoke, Va.

Dr George F Cahill, New York, "The Medical and Surgical Treatment of Calculous Anuria" Discussed by Drs Harry R Trattner, Cleveland, Ernest M Watson, Buffalo, and George F Cahill, New York.

Dr Frederic E B Foley, St Paul, "Management of Ureteral Stone: Operation Versus Expectancy and Manipulation" Discussed by Drs William J Engel, Cleveland, F C Herrick, Cleveland, and Frederic E B Foley, St Paul.

Dr Abraham Ravich, Brooklyn, "Present-Day Management of Bladder Stones, with a Description of Visualized Litholapaxy".

### SECTION ON ORTHOPEDIC SURGERY

#### WEDNESDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2:10 by the chairman Dr James S Speed, Memphis, Tenn.

Dr J E M Thomson, Lincoln, Neb, read a paper on "The Treatment of Communitated Fracture of the Patella in Which There Are One Large Fragment and Several Small Fragments" Discussed by Drs James S Speed, Memphis, Tenn, H R Conn, Akron, Ohio, Marcus H Hobart, Evanston, Ill, H W Orr, Lincoln, Neb, and Frank R Ober, Boston.

Dr Louis G Howard, Boston, read a paper entitled 'Report of One Hundred Cases of Fracture of the Hip' Discussed by Drs Archibald F O'Donoghue, Sioux City, Iowa, J Laurence Jones, Kansas City, Mo, and G A Hendon, Louisville, Ky.

Drs Halford Hallock and James W Toumey Jr, New York, presented a paper on 'End Result Study of Tuberculosis of the Hip Joint Treated by Fusion: A Study of One Hundred and Seventy Cases' Discussed by Drs Henry W Meyerding, Rochester, Minn, Frank R Ober, Boston, C H Heyman, Cleveland, and Joseph S Barr, Boston.

Dr Rex L Diveley, Kansas City, Mo, read a paper on "The Treatment of Simple Foot Imbalance" Discussed by Drs Carl E Badgley, Ann Arbor, Mich, Theodore A Willis, Cleveland, Lewis Clark Wagner, New York, and J J Kurlander, Cleveland.

Dr Voigt Mooney, Pittsburgh, read a paper on "Nonoperative Treatment of Fractures of the Bones of the Forearm, with Special Reference to the Treatment of These Fractures in Children and Adolescents: A Report of One Hundred and Fifty Consecutive Recent Cases" Discussed by Drs Rudolph S Reich, Cleveland, and Wallace S Duncan, Cleveland.

Drs Arthur G Davis and E L Armstrong, Erie, Pa, presented a paper on "The Epiphyseal Growth Disk" Discussed by Drs J A Key, St Louis, and Maxwell Harbin, Cleveland.

#### THURSDAY, JUNE 14—AFTERNOON

Dr Paul Crenshaw Colonna, New York, read a paper on "Congenital Pseudarthrosis of the Tibia" Discussed by Drs Philip Lewin, Chicago, and Oscar L Miller, Charlotte, N C.

Dr James Warren Sever, Boston, read a paper on "Nonunion in Fractures of the Shaft of Humerus: A Report on Four Cases" Discussed by Drs William B Owen, Louisville, Ky, and William L Sneed, New York.

Dr James S Speed, Memphis, Tenn, read the chairman's address entitled "An Analysis of End Results in the Treatment of Central Fractures of the Neck of the Femur".

Dr Sumner L S Koch, Chicago, read a paper on "Disabilities of the Hand Resulting from Loss of Joint Function" Discussed by Drs Walter G Stern, Cleveland, Arthur Steindler, Iowa City, and L E Papurt, Cleveland.

Drs Arthur Steindler, Ernest Freund, and Jacob Kulowski, Iowa City, presented a paper on "Statistical Analysis and Report on the Treatment of Five Hundred Cases of Congenital Dislocation of the Hip: Bloodless and Open Reduction and Late Palliative Operations" Discussed by Drs Joseph A Freiberg, Cincinnati, and Samuel L Robbins, Cleveland.

Dr Theodore P Brookes, St Louis, read a paper on "Dislocations of the Cervical Spine: Some Predisposing Causes" Discussed by Drs Robert D Schrock, Omaha, and Carl B Davis, Chicago.

Dr Charles N Pease, Chicago, read a paper on "Injuries to the Vertebrae and Intervertebral Disks Following Lumbar Puncture" Discussed by Drs Edward L Compere, Chicago, C G Barber, Cleveland, E Bennette Henson, Charleston, W Va, and L E Papurt, Cleveland.

#### FRIDAY, JUNE 15—AFTERNOON

The following officers were elected chairman, R D Schrock, Omaha, vice chairman, A T Legg, Boston, secretary, Fremont A Chandler, Chicago, delegate, Henry W Meyerding, Rochester, Minn, alternate, James Warren Sever, Boston.

Dr Sylvan L Haas, San Francisco, read a paper on "Treatment of Permanent Paralysis of Deltoid Muscle with Luxation at the Shoulder Joint" Discussed by Drs James A Dickson, Cleveland, A H Brewster, Boston, Robert D Schrock, Omaha, and Walter A Hoyt, Akron, Ohio.

Dr Joel E Goldthwait, Boston, read a paper on "The Mechanics of the Function of the Viscera in the Upper Part of the Abdomen" Discussed by Drs F C Kidner, Detroit, and Emil D Hauser, Chicago.

Drs Albert B Ferguson and M Beckett Howorth, New York, presented a paper on "Coxa Magna: A Condition of the Hip Related to Coxa Plana" Discussed by Dr Oscar L Miller, Charlotte, N C.

Dr C Howard Hatcher, Chicago, read a paper on 'The Changes in Autogenous Bone Transplants' Discussed by Drs Eshe Asbury, Cincinnati, and Sylvan L Haas, San Francisco.

Dr R A Griswold, Louisville, Ky, read a paper on "Fracture of Both Bones of the Leg: Treatment by a Modified Boehler Method with a New Apparatus" Discussed by Drs William B Owen, Louisville, Ky, J A Caldwell, Cincinnati, Maxwell Harbin, Cleveland, F G Murphy, Chicago, Ralph G Carothers, Cincinnati, and Edson B Fowler, Evanston, Ill.

Dr R Plato Schwartz, Rochester, N Y, read a paper on "The Influence of the Shoe on Gait as Recorded by Electro-

basograms and Slow Motion Pictures" Discussed by Drs Ernst Freund, Iowa City, G I Bauman, Cleveland, and Robert Johnson, Baltimore

## SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

WEDNESDAY, JUNE 13—MORNING

The meeting was called to order at 9 05 by the chairman, Dr Albert F R Andresen, Brooklyn

The chairman announced the appointment of Dr Sidney K Simon, New Orleans, as third member of the Executive Committee in place of Dr George B Eusterman

Dr Ernest H Gaither, Baltimore, presented the following resolution

WHEREAS The Section on Gastro Enterology and Proctology of the American Medical Association at its regular meeting in June 1933 adopted a resolution favoring the organization of an American Board of Gastro Enterology and authorized the appointment by the chairman of three members to serve on this board and

WHEREAS At its meeting on April 30 1934 the American Gastro Enterological Association also approved the formation of a Board of Gastro Enterology and appointed four members to serve on this board be it

Resolved That the chairman of this section be directed to appoint another fourth member for the purpose of equalizing the representation of this section on the American Board of Gastro Enterology with that of the American Gastro-Enterological Association

On motion by Dr Sidney K Simon, New Orleans, seconded by Dr Anthony Bassler, New York the resolution was adopted

Dr Lewis Gregory Cole New York read a paper on 'The Morphology and Function of a Continuous Reticular Coat of the Small Intestine' Discussed by Drs Eugene P Pendergrass, Philadelphia, Frank Smithies, Chicago, and Lewis Gregory Cole, New York

Dr John L Kantor, New York, read a paper on 'Regional (Terminal) Ileitis Its Roentgen Diagnosis' Discussed by Drs Harry M Weber Rochester, Minn James T Case Chicago Anthony Bassler, New York Burrill B Crohn New York, John L Kantor, New York, and Frank Smithies, Chicago

Drs Russell S Boles and Jacob Gershon-Cohen, Philadelphia read a paper on "Intestinal Tuberculosis An Analysis of One Thousand Autopsies, with Remarks on the Early Diagnosis by Double Contrast Barium Enema" Discussed by Drs Irving Gray, Brooklyn, and Russell S Boles Philadelphia

Dr Asher Winkelstein, New York, read a paper on 'Peptic Esophagitis A New Clinical Entity' Discussed by Drs Chevalier Jackson, Philadelphia, Rudolph Kramer New York, Henry A Rafsky, New York, Herman J Moersch, Rochester, Minn, and Asher Winkelstein New York

Drs Chevalier Jackson and Chevalier L Jackson, Philadelphia presented a paper on Gastroscopy" Discussed by Drs Gabriel Tucker, Philadelphia William A Swalm, Philadelphia, Samuel Weiss, New York, Edward B Benedict Boston and Chevalier Jackson, Philadelphia

Drs Claude C Tucker and C Alexander Hellwig Wichita Kan, presented a paper on "Histopathology of the Anal Crypts" Discussed by Drs Charles E Pope Evanston, Ill Curtice Rosser, Dallas Texas, John L Jelks, Memphis, Tenn, V K Allen Tulsa, Okla, and Claude C Tucker, Wichita, Kan

THURSDAY, JUNE 14—MORNING

Dr Albert F R Andresen, Brooklyn, read the chairman's address, entitled "The Undergraduate Teaching of Gastro Enterology in American Medical Schools"

Dr Anthony Bassler New York, read a paper on "Digestive Manifestations of Gout and Their Treatment" Discussed by Drs Horace W Soper, St Louis E W Shank, Dayton Ohio Philip S Hench Rochester, Minn and Anthony Bassler, New York

Drs Sidney A Portis and J S Grove, Chicago presented a paper on Gastro-Intestinal Manifestations of Urologic Disease Discussed by Drs Harlow Brooks New York Charles M McKenna Chicago Julius Friedenwald Baltimore Leon Bloch Chicago, Anton W Oelgoetz Columbus Ohio, and Sidney A Portis Chicago

Drs F C Mann and J L Bollman, Rochester, Minn read a paper on "Jaundice A Review of Experimental Investigations"

Dr David H Rosenberg, Chicago, read a paper on "The Galactose and Urobilinogen Tests in the Differential Diagnosis of Obstructive and Intrahepatic Jaundice"

Drs H M Rozendaal, M W Comfort and A M Snell, Rochester, Minn, read a paper on "Latent and Slight Jaundice The Significance of Slightly Elevated Concentrations of Serum Bilirubin"

These three papers were discussed by Drs I S Ravdin Philadelphia A C Ivy, Chicago, M A Blankenhorn, Cleveland, Leon Schiff, Cincinnati, A H Aaron, Buffalo V C Rowland Cleveland, I R Jankelson, Boston Franklin W White Boston, Harry Shay, Philadelphia, Norman W Elton, Reading, Pa, Frank Smithies, Chicago, Frank S Perkin Detroit, Hyman I Goldstein, Camden N J, Frank C Mann, Rochester, Minn, David H Rosenberg, Chicago, and M W Comfort, Rochester, Minn

Dr Clement L Martin, Chicago, read a paper on "Gonococcal Infection of the Rectum" Discussed by Drs Herbert T Hayes, Houston, Texas Curtice Rosser, Dallas, Texas Claude C Tucker Wichita Kan, and Clement L Martin Chicago

The chairman announced the appointment of Dr Adolph Sachs Omaha, to serve on the American Board of Gastro-Enterology in addition to the three members appointed last year, Drs Frank Smithies Chicago, H L Bockus, Philadelphia, and Albert F R Andresen, Brooklyn

FRIDAY, JUNE 15—MORNING

The following officers were elected chairman, Dr Walter A Fansler, Minneapolis, vice chairman, Dr Ernest H Gaither, Baltimore, secretary, Dr Henry L Bockus, Philadelphia delegate, Dr Curtice Rosser Dallas, Texas, alternate, Dr Frank D Gorham, St Louis

On motion of Dr Curtice Rosser, Dallas, Texas, seconded by Dr Ernest H Gaither Baltimore, the following resolution was adopted

At the request of the American Proctologic Society the committee appointed in 1933 to cooperate with a similar committee from that society in the establishment of a national board on proctology is hereby increased from three to four in number the additional member to be appointed by the new chairman of this section

The chairman announced that the additional member would be appointed by the incoming chairman

Dr Joseph W Ricketts, Indianapolis, read a paper on "Cancer of the Rectum" Discussed by Drs Dudley A Smith San Francisco Curtice Rosser, Dallas, Texas Jerome M Lynch, New York, and Joseph W Ricketts, Indianapolis

Dr F G Runyeon, Reading, Pa read a paper on "Krukenberg Tumor" Discussed by Drs Joseph C Bloodgood Baltimore, Harry E Bacon Philadelphia, Julius Friedenwald, Baltimore, and F G Runyeon Reading Pa

Dr Martin E Rehfuss Philadelphia, read a paper on 'Proteins Versus Carbohydrates A Study of Their Gastric Digestion' Discussed by Drs J Earl Thomas, Philadelphia, Ernest H Gaither Baltimore, Anthony Bassler, New York Frank Smithies, Chicago, and Martin E Rehfuss, Philadelphia

The chairman announced that the House of Delegates on Thursday afternoon passed the resolution introduced by the delegate of the section adding gastro enterology and proctology to the list of specialties approved by the American Medical Association

Drs Julius Friedenwald and Maurice Feldman, Baltimore presented a paper on "The Unstable or Irritable Duodenum Clinical Observations in One Hundred Cases" Discussed by Drs Elmer L Eggleston Battle Creek Mich, John G Mateer, Detroit Sara M Jordan Boston and Maurice Feldman Baltimore

Dr Andrew B Rivers Rochester Minn read a paper on Pain in Benign Ulcers of the Esophagus Stomach and Small Bowel The Diagnostic Significance of Type and Radiation with Some Observations of Pain Conduction Pathways Discussed by Drs Ralph C Brown Chicago Frank Smithies Chicago Sidney K Simon, New Orleans A H Aaron Buffalo and Andrew B Rivers Rochester, Minn

Drs Sara M Jordan and Everett D Kiefer, Boston, presented a paper on "Complications of Peptic Ulcer Their Prognostic Significance" Discussed by Drs Burrill B Crohn, New York, J Tate Mason, Seattle, Henry A Rafsky, New York, Julius Friedenwald, Baltimore, Walter L Palmer, Chicago, Ralph C Brown, Chicago, and Sara M Jordan, Boston

## SECTION ON RADIOLOGY

WEDNESDAY, JUNE 13—MORNING

The meeting was called to order at 9 10 by the chairman, Dr A U Desjardins, Rochester Minn

Dr W E Chamberlain, Philadelphia, was appointed to serve on the Executive Committee in place of Dr Henry K Pancoast, Philadelphia, who was absent

Dr A U Desjardins, Rochester, Minn read the chairman's address, entitled The Etiology of Lymphoblastoma

Drs Paul C Hodges Alexander Brunswick and S P Perry, Chicago, presented a paper on The Role of X-Ray Wavelength in Skin Tolerance" Discussed by Drs A U Desjardins, Rochester, Minn, and Otto Glasser, Cleveland

Drs J M Martin and Charles L Martin Dallas, Texas, presented a paper on 'A Modified Coutard X Ray Technic for Cancer Therapy" Discussed by Drs Douglas Quick, New York, E L Rybins, Iowa City, G E Pfahler, Philadelphia, Robert G Lenz, New York, A G Ray Jackson, Ohio, and I S Trostler, Chicago

Drs G E Pfahler and Jacob H Vastine, Philadelphia presented a paper on 'The Roentgen Diagnosis of Tumors of the Bladder and Their Serial Study Under Treatment by Irradiation" Discussed by Drs Russell S Ferguson, New York, B S Baringer, New York, and Leo Dolan, Toledo, Ohio

Dr Frank E Adair, New York, read a paper on "Radiologic Aspect of Cancer of the Breast from Memorial Hospital Discussed by Drs W D Cutter, Chicago, Joseph C Bloodgood, Baltimore, Albert Soiland, Los Angeles, and Dr John T Murphy, Toledo, Ohio

Drs Frank E Butler and Ivan M Wooley, Portland Ore, presented a paper on Roentgen Therapy in Chronic Paranasal Sinusitis A Further Report Discussed by Drs A U Desjardins, Rochester, Minn, Ralph S Fenton, Portland, Ore, G A Robinson, New York and John D Osmond, Cleveland

THURSDAY, JUNE 14—MORNING

Drs W Edward Chamberlain and Barton R Young, Philadelphia, presented a paper on Roentgen Evidence of Ossification (So Called Calcification) of Normal Laryngeal Cartilages Mistaken for Foreign Body" Discussed by Drs Chevalier Jackson, Philadelphia, and Samuel Brown, Cincinnati

Drs E V Allen and John D Camp, Rochester Minn, presented a paper on "Arteriography in Peripheral Vascular Disease" Discussed by Drs Urban Maes, New Orleans, Dr Herman E Pearse, Rochester N Y, and Irving Wright, New York

Dr Russell L Haden, Cleveland read a paper on Classification and Differential Diagnosis of the Anemias

Dr Roy R Kraeke, Emory University, Ga read a paper on Differential Diagnosis of the Leukemic States, with Particular Reference to the Immature Cell Types

Dr Raphael Isaacs, Ann Arbor, Mich read a paper on The Relation of Cell Types in Leukemia to Sensitivity to Radiation

Drs Nathan Rosenthal and William Harris, New York, presented a paper on Leukemia Its Diagnosis and Treatment

These four papers were discussed by Drs Charles A Doan, Columbus, Ohio, Victor Levine, Chicago, W Edward Chamberlain, Philadelphia, George J Kastlin, Pittsburgh, A U Desjardins, Rochester Minn, John T Murphy, Toledo, Ohio, and I S Trostler, Chicago

FRIDAY, JUNE 15—MORNING

The following officers were elected chairman Dr John W Pierson, Baltimore, vice chairman Dr Bernard Nichols, Cleveland, secretary, Dr John T Murphy, Toledo, Ohio, delegate

Dr Albert Soiland, Los Angeles, alternate, Dr Eugene P Pendergrass, Philadelphia

Dr Albert Soiland, Los Angeles, presented the following resolution

WHEREAS, The International Congress of Radiology which convenes every three years has already had three such meetings abroad in London in 1925 in Stockholm in 1928 in Paris in 1931 and now in Zurich in 1934 and

WHEREAS, The radiologists of the United States desire to invite the European radiologists to America for the 1937 convention and

WHEREAS, In the opinion of the members of the Section on Radiology of the American Medical Association such an international meeting would at this time engender a national good feeling and would be of high value to scientific radiology be it therefore

Resolved That the House of Delegates of the American Medical Association authorize the Section on Radiology to cordially invite the fifth International Congress to be held in America at such time and place as may be decided on by the International Committee of the fifth Congress of Radiology

On motion of Dr G W Grier, Pittsburgh, seconded by Dr Ursus V Portmann, Cleveland the resolution was adopted

Dr Albert Soiland, Los Angeles, offered also the following resolutions and moved their adoption

WHEREAS, It has been reported to the officers and members of the Section on Radiology of the American Medical Association that an intolerable condition exists between certain otherwise acceptable hospitals and their departments of radiology and

WHEREAS, It is known that in several such hospitals the business management does the collective bargaining for x ray business with staff members and outsiders to the detriment and the professional and financial loss of their staff roentgenologists and

WHEREAS, Such practice is not only unethical but places such hospitals on a direct competitive medical practice basis with their respective roentgenologists which practice has been declared illegal in several states and

WHEREAS, The practice of roentgenology or radiology is ipso facto the practice of medicine and cannot be separated therefrom be it therefore

Resolved That the House of Delegates of the American Medical Association go on record as opposing the exploitation of members of their own body in the manner outlined and be it further

Resolved That the House of Delegates of the American Medical Association in session duly assembled order this resolution referred to the Council on Medical Education and Hospitals for the study and formulation of plans tending to the abatement of these highly unprofessional and obnoxious evils

The resolutions were seconded by Dr G W Grier, Pittsburgh, and adopted

Dr Eugene P Pendergrass, Philadelphia, presented the following resolution and moved its adoption

The Section on Radiology of the American Medical Association recommends that the American Medical Association through its Bureau of Medical Economics make a complete survey of the radiologic departments of hospitals throughout the United States with special reference to the relation of radiologists to the hospital from a professional and economic standpoint

The motion was seconded by Dr L R Sante, St Louis, and adopted

Dr Edgar P McNamee, Cleveland, presented a paper on "Intrahepatic Gallbladder" No discussion

Drs Edgar C Baker and John S Lewis Jr, Youngstown, Ohio presented a paper on 'Comparison of the Urinary Tract in Pregnancy and in Pelvic Tumors" Discussed by Dr George C Prather, Boston

Drs Karl Kornblum and Leslie H Osmond, Philadelphia, presented a paper on The Effect of Intracranial Tumors on the Sella Turcica" Discussed by Drs M C Sosman, Boston, and John D Camp, Rochester Minn

Drs Stage D Blackford and Vincent W Archer, University, Va presented a paper on Pulmonary Manifestations in Human Tularemia

Dr B P Stivelman, New York read a paper on Interlobar Pleural Effusions

Dr Henry K Taylor, New York, read a paper on 'Interpretation of Roentgenographic Pathology in Pulmonary Tuberculosis'

Dr Franklin B Bogart, Chattanooga, Tenn read a paper on Early Diagnosis of Fulminating Pulmonary Tuberculosis in Adults Necessity for Repeated Roentgen Examinations"

These four papers were discussed by Drs L R Sante, St Louis, Kennon Dunham, Cincinnati, Eugene P Pendergrass, Philadelphia, James L Dubrow, Des Moines, Iowa, and G E Pfahler, Philadelphia

## SECTION ON MISCELLANEOUS TOPICS

## Session on Forensic Medicine

WEDNESDAY, JUNE 13—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Ludvig Hektoen, Chicago.

Dr. Oscar T. Schultz, Evanston, Ill., read a paper on "Reform of County Government and the Office of Coroner." Discussed by Drs. H. R. Fishback, Chicago, Timothy Leary, Boston, M. Scott Kearns, Cincinnati, and Oscar T. Schultz, Evanston, Ill.

Dr. Charles Norris, New York, read a paper on "The Office of the Chief Medical Examiner of New York City as a Medico-legal Center." No discussion.

Dr. Timothy Leary, Boston, read a paper on "Subdural Hemorrhage." Discussed by Drs. Milton Helpert, New York, and Timothy Leary, Boston.

Drs. Samuel A. Levinson and Clarence W. Muehlberger, Chicago, presented a paper on "An Introductory Course in Legal Medicine for Medical Students." Discussed by Drs. J. M. Looney, Worcester, Mass., and Clarence W. Muehlberger, Chicago.

Dr. Karl Landsteiner, New York, read a paper on "Forensic Application of Serologic Individuality Tests." Discussed by Drs. Alexander S. Wiener, Brooklyn, Herman A. Heise, Milwaukee, and Karl Landsteiner, New York.

Dr. Herman A. Heise, Milwaukee, read a paper on "Alcohol and Automobile Accidents." Discussed by Drs. Alexander O. Gettler, New York, H. A. Rothrock, Jr., Bethlehem, Pa., Charles Norris, New York, W. C. Woodward, Chicago, and Herman A. Heise, Milwaukee.

Dr. Alexander O. Gettler, New York, read a paper on "The Isolation of Volatile Poisons from Tissues and Their Identification." Discussed by Dr. Harrison S. Martland, Newark, N. J.

Dr. William D. McNally, Chicago, read a paper on "The Medico-legal Aspect of Silicosis." Discussed by Drs. Henry C. Sweany, Chicago, and Morris Davidson, New York.

Dr. Milton Helpert, New York, read a paper on "An Epidemic of Fatal Estivo-Autumnal Malaria Among Drug Addicts

in New York City Transmitted by Common Use of Hypodermic Syringe." Discussed by Dr. Charles Norris, New York.

Dr. Harrison S. Martland, Newark, N. J., read a paper on "Carbon Monoxide Poisoning." Discussed by Drs. James N. Patterson, Cincinnati, Alexander O. Gettler, New York, William D. McNally, Chicago, and Harrison S. Martland, Newark, N. J.

On motion by Dr. Harrison S. Martland, duly seconded and carried, it was voted that the section organize a committee for the purpose of acquainting the suitable authorities in the legal profession with the existence and reliability of the blood grouping tests, so that statutes may be enacted authorizing courts to order individuals to submit to blood grouping tests when they are required, in those jurisdictions in which blood tests are not obligatory at present.

On motion by Dr. Oscar T. Schultz, Evanston, Ill., seconded by Dr. Harrison S. Martland, Newark, N. J., it was voted that the section, through the secretary, express its appreciation to the proper officials of the American Medical Association for the privilege of having held this meeting, of the necessity and advisability of future meetings of this section at other meetings of the Association, and that a committee be appointed to study the question of the advisability of future meetings.

## Session on Nutrition

THURSDAY, JUNE 14—AFTERNOON

Dr. James S. McLester, Birmingham, Ala., read the chairman's address, entitled "Changing Concepts of Nutrition."

Dr. S. W. Clausen, Rochester, N. Y., read a paper on "Nutrition and Resistance to Infection." Discussed by Drs. J. R. Gerstley, Chicago, and S. W. Clausen, Rochester, N. Y.

Dr. H. R. Geyelin, New York, read a paper on "The Treatment of Diabetes with Insulin (After Ten Years)."

Dr. Walter Bauer, Boston, read a paper on "What Should a Patient with Arthritis Eat?" Discussed by Dr. L. Maxwell Lockie, Buffalo.

Dr. Thomas T. Mackie, New York, read a paper on "Ulcerative Colitis. II. The Factor of Deficiency States. A Clinical Study."

## THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the Cleveland session was the largest in the history of the Association. All fifteen sections of the Scientific Assembly participated through special section exhibit committees appointed for the purpose, while sixty-three individuals reading papers before the various sections also had exhibits on the same subjects.

There were three special exhibits authorized by the Board of Trustees. The exhibit on encephalitis, a cooperative undertaking by the Committee on Scientific Exhibit, with the United States Public Health Service, placed special stress on certain features of the 1933 outbreak, a pamphlet prepared by Theodore C. Hempelmann, St. Louis, was distributed. The committee in charge consisted of James P. Leake, Washington, D. C., Ralph S. Muckenfuss, St. Louis, and Ralph C. Williams, chairman, Washington, D. C.; this committee was assisted by the following demonstrators: E. K. Musson, Jefferson City, Mo.; Charles Armstrong, Washington, D. C.; and from St. Louis, H. D. Chope, H. A. McCordock, W. D. Collier, Elizabeth Moore, J. E. Smadel, R. A. Kinsella, T. C. Hempelmann, and G. C. Brown.

The exhibit on nutrition was conducted in conjunction with the session on nutrition in the Section on Miscellaneous Topics. The exhibit, presented under the joint auspices of the Committee on Scientific Exhibit, the Committee on Foods, and Hygiene, the Health Magazine was under the direction of a committee composed of Walter C. Alvarez, Rochester, Minn., Reginald Fitz, Boston, and P. C. Jeans, Iowa City, assisted by a competent corps of demonstrators. A pamphlet on nutrition prepared for the occasion, was distributed at the exhibit.

The special demonstrations in pathology were presented under the direction of Benjamin S. Kline, Cleveland, assisted by a group of local pathologists. In addition to the continuous demonstrations in the booth, practical talks were given at

stated intervals in a space adjoining the exhibit by R. S. Reichle, Rafael Dominguez, A. R. Moritz, A. M. Young, Allen Graham, H. T. Karsner, Harry Goldblatt, and B. S. Kline, all of Cleveland.

Among the section exhibits there were several special features. The Section on Ophthalmology presented a comprehensive display on first aid in eye injuries and distributed a pamphlet on the same subject to supplement the exhibit, the Section on Obstetrics, Gynecology and Abdominal Surgery had an exhibit on home delivery technique and also showed motion pictures in an area adjoining the exhibit, the Section on Dermatology and Syphilology presented a symposium on cutaneous allergy, the Section on Practice of Medicine showed motion pictures on a prearranged schedule.

There were several symposiums to which exhibitors from different sections contributed with highly profitable results. The symposium on the treatment of burns was a cooperative undertaking sponsored by the Section on Surgery, General and Abdominal, the Section on Practice of Medicine, and the Section on Pathology and Physiology. Besides nine exhibits dealing with various phases of the subject there was a motion picture program shown in an adjoining area.

The symposium on amebiasis included contributions from the Section on Gastro-Enterology and Proctology, the Section on Pathology and Physiology, the Section on Pharmacology and Therapeutics, and the Section on Preventive and Industrial Medicine and Public Health.

The group of exhibits on thyroid diseases was presented through the cooperation of the Section on Practice of Medicine, the Section on Surgery, General and Abdominal, the Section on Pharmacology and Therapeutics, and the Section on Pathology and Physiology.

There were 162 individual exhibits open to medal awards, nineteen educational exhibits and five special exhibits sponsored by the Committee on Scientific Exhibit or by section exhibit committees, making a total of 186 exhibits. There were 364 persons identified with the various exhibits.

## REPORT OF THE COMMITTEE ON AWARDS

The Committee on Awards made the following report

### CLASS I

[Awards in Class I are made for exhibits of individual investigations, which are judged on the basis of originality and excellence of presentation]

The gold medal to Gregory Schwartzman Mount Sinai Hospital, New York, for original investigations of skin reactivity to bacterial filtrates, its role in immunology and its practical applications

The silver medal to Timothy Leary Boston for original work on the relation of cholesterol to atherosclerosis

The bronze medal to Charles C Higgins, Cleveland Clinic, Cleveland, for original work on experimental production and solution of urinary calculi

Certificates of merit, Class I, are awarded to the following (alphabetically arranged)

Herrman L Blumgart, J E F Riseman David Davis and A A Weinstein, with the surgical collaboration of David D Berlin, Beth Israel Hospital and Harvard Medical School, Boston, for exhibit illustrating the treatment of angina pectoris and congestive failure by removal of the thyroid

Roy R Kracke and Francis P Parker, Emory University School of Medicine, Atlanta, Ga for exhibit illustrating the knowledge of the etiology of granulopenia

Jane Sands Robb and J G Fred Hiss, Syracuse University College of Medicine, Syracuse, N Y, for exhibit illustrating the individual cardiac muscles

Philips Thygeson, University of Iowa, Iowa City for exhibit on the laboratory diagnosis of certain conjunctival diseases

In addition, the following exhibits are deemed worthy of Honorable Mention (alphabetically arranged)

That of Thomas B Magath, Mayo Clinic, Rochester, Minn for excellence in illustrating the lesions of amebiasis and the life history of *Endamoeba histolytica*

That of T O Menees, and J D Miller, Blodgett Memorial Hospital, Grand Rapids, Mich, for study of the endometrium by means of thorium hydroxide solutions

That of George C Shivers, University of Colorado Medical School, Colorado Springs, for exhibit illustrating the avoidance of pulmonary embolism from intravenous arsenicals

### CLASS II

[Awards in Class II are made for exhibits which do not exemplify purely experimental studies and which are judged on the basis of excellence of correlating facts and excellence of presentation]

The gold medal to Lewis B Bates, Lawrence Getz, Ernesto Icaza and William M James, Medical Association of the Isthmian Canal Zone Panama City, for excellence of presentation of an exhibit illustrating diagnosis and pathology of human amebiasis

The silver medal to Claude S Beck, Western Reserve University School of Medicine, and Lakeside Hospital, Cleveland for excellence of presentation of exhibit illustrating circulatory failure produced by compression of the heart and curable by operation

The bronze medal to William P Murphy, Peter Bent Brigham Hospital, Boston, for excellence of presentation of exhibit illustrating the therapeutic effects of intramuscular injections of liver extract in pernicious anemia and in secondary anemia

Certificates of merit, Class II, are awarded to the following (alphabetically arranged)

Vincent W Archer S D Blackford and J E Wissler, University of Virginia Hospital, University Va for excellence of presentation of an exhibit on radiologic observations of the pulmonary changes in tularemia

Russell L Haden, Cleveland Clinic, Cleveland for excellence of presentation of an exhibit illustrating the examination of the blood

Byrard T Horton, Mayo Foundation, Rochester, Minn, for excellence of presentation of an exhibit illustrating congenital arteriovenous fistula of the extremities

R R Jones, United States Public Health Service, Washington, D C for an exhibit illustrating the control of the lead hazard in industry

In addition, the following exhibits are deemed worthy of Honorable Mention (alphabetically arranged)

That of Lloyd Arnold and C J Gustafson, University of Illinois College of Medicine, Chicago, for an exhibit on normal menstruation

That of John D Camp, Mayo Foundation for Medical Education and Research, Rochester, Minn, for exhibit of roentgenographic study of the osseous changes in tumors of the spinal cord

That of W Edward Chamberlain and Barton R Young Temple University Medical School, Philadelphia, for exhibit on primary bone tumors

That of Wallace B Hamby and W James Gardner, Cleveland Clinic, Cleveland, for exhibit on intracranial neoplasms

That of Edwin E Osgood, Clarice Ashworth and Richard Young University of Oregon Medical School, Portland, Ore, for exhibit on morphologic hematology

A special certificate of merit is awarded to A W Adson, W McK Craig, J G Love, H W Woltman, F P Moersch, W D Shelden and J W Kernohan, Mayo Clinic and Mayo Foundation, Rochester, Minn, for the excellence of their exhibit on neurologic diseases and neurosurgical procedures

### EDUCATIONAL CLASSIFICATION

A special certificate of merit is awarded to the Chicago Board of Health for its exhibit illustrating the Chicago outbreak of amebiasis

The committee also wishes to emphasize especially the cooperation with the American Medical Association, of the government and of various national and local organizations in providing educational exhibits to show the progress of organized activities for the promotion of health and the prevention of disease

### SPECIAL COMMENDATION

The Committee on Awards desires to commend especially the following exhibits

Those exhibits illustrating the symposium on the treatment of burns sponsored by the Section on Surgery, General and Abdominal, Section on Practice of Medicine and Section on Pathology and Physiology

The group of exhibits sponsored by the Section on Dermatology and Syphilology

The group of exhibits on Growth and Repair from the Department of Anatomy and Associated Foundations, Western Reserve University School of Medicine

The exhibit of Victor C Myers, E Muntwyler, F C Bing R F Hanzal and C T Way, Western Reserve University School of Medicine, illustrating biochemical diagnostic methods

The Committee on Awards wishes to draw to the attention of the section exhibit committees, and through them the Committee on Scientific Exhibit, the fact that a large percentage of the exhibits are based on observation and a much smaller percentage on actual experimentation. While realizing the value of accurate observation in medicine and recognizing that the physician in general practice must ever be kept in mind in the presentation of exhibits, the Committee on Awards recommends that greater efforts be made to secure exhibits representing the most recent advances in experimental medical investigations

The Committee on Awards believes that the policy of correlating the Scientific Exhibit with the Scientific Assembly by the appointment of section exhibit committees is advantageous, and it is noted with satisfaction that all the sections now have appointed such committees. The attention of the section officers is respectfully directed to the fact, however, that the section exhibit committees must be chosen with great care so that the most noteworthy research in the various specialties may be represented in the Scientific Exhibit

The Committee on Awards views with favor the grouping of subjects in symposiums as portrayed this year by the exhibits on burns, amebiasis and thyroid diseases

The Committee on Awards wishes to commend the large number of individual exhibitors who have developed their exhibits entirely from their own resources and without financial aid

The Committee on Awards desires to call attention to the special exhibits sponsored by the American Medical Association, as follows: nutrition pathologic demonstrations and the 1933 outbreak of encephalitis. Especial commendation is given to the physicians who have assisted in the preparation and presentation of these special exhibits with a particular vote of thanks to Dr Theodore C Hempelmann, St Louis, who prepared the manuscript for the pamphlet on encephalitis, and to the committees that prepared and assembled the special exhibits on eye injuries and home delivery technic. By their participation in these special exhibits these men are excluded from the opportunity of competing for individual awards that might have been merited by a number of them. The exhibit on the 1933 outbreak of encephalitis merits special commendation.

The Committee on Awards wishes to take this occasion to render for the medical profession an expression of appreciation to the members of the various section exhibit committees and to the Committee on Scientific Exhibit of the Board of Trustees for their untiring efforts, and especially to Dr D Chester Brown, who is now completing his term on the Board of Trustees after a period of fourteen years as chairman of the Committee on Scientific Exhibit.

The Committee on Awards believes that the members and Fellows of the American Medical Association owe a debt of gratitude to the Committee on Scientific Exhibit to the Advisory Committee, and to Dr Thomas G Hull, executive in charge of the arrangements of the Scientific Exhibit. The Committee cannot commend too highly the appropriate arrangements general and special, the excellent management, the instructiveness and the scientific as well as the practical value of the exhibit. Many physicians and investigators, often at great personal sacrifice, have presented exhibits dealing with various aspects of the specialties in medicine, prepared by means of modern methods and devices for the visualization of the most recent advances in medicine.

LUDVIG HEKTOEN, Chairman, Chicago  
E J CAREY, Milwaukee  
TEMPLE FAY, Philadelphia  
ROGER I LEE, Boston  
JAMES D TRASK, New Haven

## Association News

### COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

#### Abstract of Minutes of the Council Business Meeting held at Cleveland, June 10

1 The Council recommended the appointment of a committee to appraise the aims and methods of medical education. Dr Ray Lyman Wilbur, the chairman, accordingly appointed the following committee: Dr Reginald Fitz (chairman), Dr Waller S Leathers, Dr Willard C Rappley, Rev Alphonse M Schwitalla, Dr Dean Lewis and Dr Harold Rypins.

2 Representatives of the University of Georgia School of Medicine appeared before the Council and presented plans for the rehabilitation of the medical school. In particular, it was requested that the school be permitted to carry on its program during the next academic year without penalizing those students who might later desire to transfer to other institutions. The Council, therefore resolved that in the resolution adopted in February 1934 the provision regarding transfer of students be amended so as to include those enrolled for the session of 1934-1935.

3 It was resolved "that hospitals outside the United States and Canada be omitted from the list of hospitals approved for the training of interns because of the difficulty of inspecting them."

4 It was resolved "that the lists of hospitals for approval or otherwise be acted on in accordance with the recommendations of the staff."

5 It was resolved "that pathologists and radiologists affiliated with unrecognized medical schools be not approved."

6 The Subcommittee on Specialists submitted the accompanying statement of the Essentials for Examining Boards in Specialties. These Essentials were then approved by the Council for presentation to the House of Delegates.

7 It was resolved "that, concerning applications of special examining boards for the Council's approval, the Council will consult the Advisory Board for Medical Specialties, provided the Advisory Board supports the standards established by the Council and with the understanding that the Council is in no way bound by recommendations of the Advisory Board."

8 It was resolved "that in the proceedings for the revocation of certificates whether conducted by a special examining board or by the Advisory Board for Medical Specialties, the Council requests that it be consulted, with the understanding that neither such special board nor the Advisory Board is bound by the Council's recommendation."

9 It was resolved "that the lists of pathologists and radiologists, submitted by the staff, be approved."

### ESSENTIALS FOR EXAMINING BOARDS IN SPECIALTIES

By THE COUNCIL ON MEDICAL EDUCATION AND  
HOSPITALS OF THE AMERICAN MEDICAL  
ASSOCIATION, CHICAGO

#### I ORGANIZATION

1 A special examining board to be approved by the Council should represent a well recognized and distinct specialty of medicine.

2 It should be composed of representatives of the national organizations of that specialty including the related section of the American Medical Association.

3 It should be incorporated.

4 A special board should

- (a) Determine whether candidates have received adequate preparation as defined by the board.
- (b) Provide a comprehensive test of the ability and fitness of such candidates.
- (c) Certify to the competence of those physicians who have satisfied the requirements of the board.

#### II DEFINITION OF SPECIAL FIELDS

The following branches of medicine at present are recognized as suitable fields for the certification of specialists:

- |                             |                               |
|-----------------------------|-------------------------------|
| 1 Internal Medicine         | 7 Dermatology and syphilology |
| 2 Surgery                   | 8 Neurology and psychiatry    |
| 3 Pediatrics                | 9 Urology                     |
| 4 Obstetrics and gynecology | 10 Orthopedic surgery         |
| 5 Ophthalmology             | 11 Radiology                  |
| 6 Otolaryngology            | 12 Pathology                  |

#### III QUALIFICATION OF CANDIDATES

Each applicant for admission to the examination should be required to present evidence that he has met the following standards:

##### A General Qualifications<sup>1</sup>

- 1 Satisfactory moral and ethical standing in the profession.
- 2 A license to practice medicine.
- 3 Membership in the American Medical Association or by courtesy membership in such Canadian medical societies as are approved by the Council on Medical Education and Hospitals of the American Medical Association. Membership in other societies should not be required.

##### B Professional Education<sup>1</sup>

- 1 Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.
- 2 Completion of an internship of not less than one year in a hospital approved by the same Council.

##### C Special Training<sup>1</sup> (to be effective not later than Jan 1, 1938)

- 1 A period of study after the internship of not less than three calendar years in clinics, dispensaries, hospitals or laboratories recognized by the same Council as competent to provide a satisfactory training in the special field of study.

<sup>1</sup> In case of an applicant whose training has been received outside the United States and Canada the credentials must be satisfactory to the Advisory Board.

- 2 This period of specialized preparation shall include
  - (a) intensive graduate training in anatomy physiology pathology and the other basic medical sciences which are necessary to the proper understanding of the disorders and treatment involved in the specialty in question
  - (b) an active experience of not less than eighteen months in hospitals clinics dispensaries or diagnostic laboratories recognized by the Council as competent in the specialty
  - (c) examinations in the basic medical sciences of a specialty as well as in the clinical laboratory and public health aspects
- 3 An additional period of not less than two years of practice

#### IN WITHDRAWAL

For reasons which are deemed sufficient in the judgment of the Council on Medical Education and Hospitals the recognition extended by the American Medical Association to holders of certificates from special examining boards may be withdrawn

### MEDICAL BROADCASTS

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Central daylight saving time. The speaker will be Dr. W. W. Bauer. The next three broadcasts will be as follows:

- July 12 A Healthful Vacation
- July 19 Entertaining the Convalescent Child
- July 26 The First Month

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC.)

### ALABAMA

**Changes at the University**—Dr. John Howard Ferguson recently of Yale University, has been named assistant professor of physiology and pharmacology at the University of Alabama School of Medicine, succeeding Dr. Gene H. Kistler who is transferring to the department of pathology and bacteriology as associate professor. Albert Sydney Harris, Ph.D., Banks has been appointed instructor in physiology and pharmacology. Dr. Kistler recently received the Joseph A. Capps Prize of \$500, awarded by the Institute of Medicine of Chicago.

**Society News**—Dr. Jay Arthur Myers, Minneapolis addressed the annual meeting of the Alabama Tuberculosis Association, April 17 on "The Child and the Tuberculosis Problem."—Dr. Howard R. Mahorner, New Orleans, spoke before the Alabama Academy of Science at Mobile recently, on "Etiology of Gout."—Dr. Roscoe C. Stewart, Sylacauga, was elected president of the Alabama Hospital Association at its annual meeting recently, Dr. Charles N. Carraway, Birmingham, and Carl A. Grote, Huntsville, vice president, and Albert C. Jackson, Jasper, secretary.

### CALIFORNIA

**Mussel Quarantine**—A quarantine on mussels has been established to cover the coast area extending from the southern boundary of Monterey County to the California-Oregon boundary, excluding San Francisco Bay. Laboratory examinations have shown that mussels from these areas are now poisonous although mussels within the bay region have shown no toxicity. The sale or offering for sale of mussels from these specified areas is prohibited during the period May 31 to September 30.

**Hospital News**—The laboratory for neuropathology in the new acute unit of the Los Angeles County Hospital has been named in honor of Dr. Santiago Ramon y Cajal, Madrid, Spain. A bronze plaque of Dr. Ramon y Cajal has been made for the director's laboratory and a bust will be placed later in the departmental library. The work of the laboratory will be under the direction of Dr. Cyril B. Courville. Dr. Ramon y Cajal has given many books to the laboratory.

**Special Meeting on Infantile Paralysis**—A special meeting was held June 28 by the pediatric section of the Los Angeles County Medical Association to consider the present epidemic of poliomyelitis in southern California. Dr. Alfred J. Scott, Jr. reported on a survey made by a special committee and Drs. George Stevens and George Roth of the city and

county health departments, respectively, the symptomatology and diagnosis. Dr. Mary F. Bigler discussed treatment. Other speakers included Drs. George Parrish and John L. Pomeroy.

**Health Survey**—The State of California Emergency Relief Administration is conducting a survey to obtain knowledge of health conditions and the extent of need for more adequate medical care. Information being sought includes the name of the family physician, whether or not medical bills are paid on an annual basis and, if so, the annual fee; the number of months since the family has received medical care; the bills accrued for this care during the past few months; and the total the family owes in medical bills. According to the *Bulletin* of the Los Angeles County Medical Association, the survey will list the persons who have been ill and the nature, degree and the period of their illnesses. It will show the nature of care received whether by physician, group clinic, public clinic, city physician or practitioners other than doctors of medicine. It will also indicate the time spent in private and public hospitals and whether or not the patients received nursing care and how much. A classification of all charges made will be included.

### COLORADO

**Society News**—Speakers before the Crowley County Medical Society in Ordway, May 9, were Drs. George P. Lingelfelter and George M. Blekensderfer, Denver, on "Diagnosis of the Commoner Skin Diseases" and "Present Status of Serum Therapy in Pediatrics" respectively.—Dr. George B. Kent, Denver, addressed the Larimer County Medical Society in Fort Collins, May 2 on "Surgical Management of Peptic Ulcer."—At a meeting of the Mesa County Medical Society in Grand Junction, May 15, Drs. Robert B. Porter, Glenwood Springs, and James S. Orr, Fruita, spoke on "Thyroid Disturbances" and "Mechanical Conditions in the Abdomen Requiring Operative Intervention," respectively.—A symposium on cancer of the breast constituted the program of the Weld County Medical Society, meeting at Greeley, May 7; speakers were Drs. Samuel B. Potter, William C. Black and William W. Wasson, Denver.—Dr. Thomas A. Stoddard discussed fibroid tumors before the Pueblo County Medical Society recently.

### CONNECTICUT

**Dr. Edwards Resigns**—Dr. Herbert R. Edwards, acting health officer of New Haven since the resignation in January of Dr. John L. Rice to become health commissioner of New York, has resigned effective May 10, to direct the tuberculosis program in New York. For the present a committee of the board of health will manage the activities of the department.

### GEORGIA

**Cancer Clinic**—Dr. George H. Semken, New York, formally opened the new cancer division in the Georgia Baptist Hospital, Atlanta, June 1. Dr. James L. Campbell is the director of the new section which will care for pay patients only. In attendance at the opening of the clinic were Drs. Dan Y. Sage, formerly president of the Fulton County Medical Society, and Clarence L. Ayers, Toccoa, president of the Medical Association of Georgia. It is planned to hold cancer conferences each Friday.

**State Medical Election**—Dr. James E. Paulin, Atlanta, was chosen president-elect of the Medical Association of Georgia at its annual session in Augusta, May 11, and Dr. Clarence L. Ayers, Toccoa, was inducted into the presidency. New vice presidents are Drs. George A. Traylor, Augusta, and Walter G. Elliott, Cuthbert, and Dr. Allen H. Bunce, Atlanta, was reelected secretary. The next annual meeting of the association will be held in Atlanta, May 7-10, 1935. The house of delegates authorized the creation of an advisory board to its council, to be composed of all living past presidents of the association who shall hold office for life. The committee on legislation was directed to draw up and sponsor at the next session of the state legislature a basic science law for Georgia. Dr. Charles H. Richardson, Macon, the outgoing president, was presented with the 'badge of service' of the association at this session in recognition of his many years of service to the profession.

### ILLINOIS

**Society News**—Dr. Robert E. Schlueter, St. Louis, addressed the Clinton County Medical Society at Breese, June 13 on cancer of the breast.—Dr. Logan Clendening, Kansas City, was the guest speaker at the eightieth anniversary celebration of the McLean County Medical Society in Bloom-

ington, May 8, his subject was "Historical Medical Books, Paintings and Places"—Dr Charles P Emerson, Indianapolis, discussed oriental medicine before the Peoria City Medical Society, June 5

**Chest Examinations at the State Fair**—Opportunity will be given to adults for chest examinations to detect heart impairment as a part of the program of the state health department at the State Fair, August 18-25, in Springfield. The examinations will include electrocardiograms in as many cases as practicable. All volunteers, so far as facilities permit, will be tested for blood pressure, height, weight and perhaps one or two other factors, such as lung capacity. Facilities for taking roentgenograms of 500 young persons between 12 and 19 years of age to detect early tuberculosis will also be available those from families with a history of the disease to be given preference. Well babies and children will also be given medical examinations

### Chicago

**Personal**—Dr William Allen Pusey delivered the Prosser White Oration before the St. John's Hospital Dermatological Society, June 27, at the Royal Society of Medicine, England, his subject was "Disease, Gadfly of the Mind, Especially the Stimulus of Disease in the Development of the Mind"

**Society News**—Dr George K Fenn was elected president of the Chicago Society of Internal Medicine at its annual meeting, recently, Dr Walter L Palmer, vice president, and Dr Clarence F G Brown, secretary—Dr Joseph Welfeld was elected president of the Chicago Urological Society at the annual meeting, May 24—Dr Julius H Hess was elected president of the Chicago Medical Society at its annual meeting, June 19, succeeding Dr Austin A Hayden

**Fraudulent Motor Club Memberships**—A salesman claiming to represent the Chicago Motor Club and the American Motorist Service Association has been selling memberships, costing from \$1 to \$3, to physicians in this territory. Mr William H Thomson of the Chicago Motor Club reports that the man is not a bona fide representative of the Chicago Motor Club and urges all physicians to get in touch with him immediately if approached by such a person. Mr Thomson states that he is not familiar with the policy of the American Motorist Service Association, which could not be located in the Chicago telephone directory. Later information from the national headquarters of the American Automobile Association indicates that this man is using the name H Hackett. It was said that he has dark hair and prominent features, weighs 170 pounds and is about 40 years old

### INDIANA

**Society News**—Dr Will W Holmes, Logansport, was elected president of the Eleventh Indiana Councilor District Medical Association at its fifty-first semiannual meeting in Kokomo, May 16, speakers included Arthur L Harter, DDS, former president of the Indiana Dental Association, on "Dental and Medical Relationship"—Dr Werner W Duenling, Fort Wayne, addressed the Adams County Medical Society in Decatur, June 8 on "Syphilis—Its Problems and Treatment"—Dr John P Gentle, New Albany, spoke before the Floyd County Medical Society in New Albany, June 8 on "Diabetes in Pregnancy"—At a meeting of the Carroll County Medical Society in Flora, June 8, Dr John A MacDonald, Indianapolis, discussed "Differential Diagnosis of Diseases of the Chest"

### IOWA

**Personal**—Dr and Mrs William A Vincent, Belle Plaine, celebrated their fiftieth wedding anniversary, May 6—Dr Lyman B Bacon, for forty-five years the only physician in Pacific Junction, has retired on account of ill health and has gone to Westboro, Mass

**Society News**—A symposium on infections of the respiratory tract was presented before the Adair County Medical Society at Greenfield, June 5, by Drs George A May, Ralph H Parker and Charles C Walker, Des Moines—At a meeting of the Jasper County Medical Society in Newton June 5, Drs Daniel J Glomset and Martin I Olsen, Des Moines, conducted a symposium on nephritis and hypertension

**Public Reception to Dr Bierring**—The Chamber of Commerce of Des Moines sponsored a public reception in honor of Dr Walter L Bierring June 22 at the Savery Hotel in recognition of his induction into the presidency of the American Medical Association. Dr Bierring has been a member of the chamber of commerce for many years. Dr John T McClintock, chairman of the administrative committee, State University of Iowa College of Medicine Iowa City, spoke in appreciation of the guest of honor

### LOUISIANA

**Society News**—The Orleans Parish Medical Society and the First and Second District Dental Society were addressed in New Orleans, June 11, by Samuel H McAfee, DDS, on "Food and Teeth," and William John Healey, DDS, "Unbalanced Occlusion and Its Relation to Adjacent Structures of the Oral Cavity." The society was addressed, June 23, by Dr Isidore L Robbins on "Use of Artificial Pneumothorax in the Treatment of Lobar Pneumonia," and Earl Z Browne "Variations in Origin and Course of the Hepatic Artery—Importance from Surgical Viewpoint"—Dr Edmund McC Connely, New Orleans, addressed the Second District Medical Society in Hahnville, May 17, on epilepsy—At a joint meeting of the Ouachita Parish and the Rapides Medical Society in Alexandria, June 4, speakers were Drs James Q Graves Monroe, on "Ileocolic Adhesions" Aurelius E Fisher, Monroe, "Ectopic Gestation" and James E Walsworth, Monroe, "Cancer of the Stomach and Colon"

### MAINE

**Society News**—Dr Alvin A Morrison addressed the Portland Medical Club, May 1, on diverticulosis and diverticulitis—At a meeting of the Kennebec County Medical Association in Togus, May 17, speakers were Drs Louis F Fallon, Augusta and Harrison L Robinson, Bangor, on "Intestinal Stasis and Sequelae" and "Hyperthyroidism," respectively—Dr George H Coombs, Augusta discussed state health work before the Washington County Medical Society in Eastport, May 22, and Drs Benjamin B Foster, Portland, talked on dermatology in general practice, and Arch H Morrell, Augusta, routine tests at the state laboratory

### MASSACHUSETTS

**State Medical Election**—Dr William H Robey, Boston was reelected president of the Massachusetts Medical Society at its annual meeting in Worcester, June 5. Other officers were also reelected, as follows: Drs Philemon E Truesdale, Fall River, vice president, Walter L Burrage, Brookline secretary, and Charles S Butler, Boston, treasurer

### MINNESOTA

**Society News**—The Hennepin County Medical Society has established a "buy and sell" department for used medical equipment in its office in the Medical Arts Building, Minneapolis. Members wishing to dispose of their instruments may leave them with the secretary

**State Medical Meeting at Duluth, July 15-18**—The eighty-first annual session of the Minnesota State Medical Association will be held at the Hotel Duluth, Duluth, July 15-18 under the presidency of Dr Francis J Savage, St Paul. The following physicians will be included on the program

Peter T Bohan Kansas City Mo Cardiac Irregularities  
Herbert H Leibold Parkers Prairie How We Treat Fractures in Rural Communities  
Donald K Bacon St Paul Blood Transfusion in the Treatment of Sepsis  
Burton Rosenholtz St Paul Statistical Analysis of 2186 Cases of Polymyositis  
Arthur F Bratrud Minneapolis Ambulant Treatment of Hernia  
John W Towey Powers Mich Pneumonitis  
Arnold Schwyzer St Paul Combined Treatment (Surgery and Radiation) in Cancer of the Breast  
Robert G Green Minneapolis Occurrence of Tularemia in Wild Animals in Relation to Human Infection  
Melvin W Binger and Norman M Keith Rochester Ascites of Indeterminate Etiology

Among other features, there will be a symposium on "Recent Acquisitions in Endocrinology." Dr Alexander B Moore professor of roentgenology, Georgetown University School of Medicine, Washington, D C, will deliver the Russell D Carman Memorial Lecture, Tuesday morning, on "Function of the Roentgenologist in the Diagnosis of Intra-Abdominal Conditions," and Clarence C Little, ScD, managing director American Society for the Control of Cancer will give the Citizens Aid Society Memorial Address, on "Recent Advances in Research on Heredity in Cancer." Scientific demonstrations will be held for one hour each morning. Meeting jointly with the state medical association will be the Northwestern Pediatric Society, the Minnesota Radiological Society, Minnesota Orthopedic Society, Minnesota Society of Neurology and Psychiatry and the Trudeau and Heart societies. The women's auxiliary will meet in McComb Hall of the Hotel Duluth Monday evening. Dr Walter L Bierring, Des Moines, Iowa President American Medical Association who will take part in

discussions before the state association, will also address the association, among others, on "Medical Practice and the Changing Order"

### MISSISSIPPI

**Personal**—Dr James M Acker Jr, Aberdeen, past president of the Mississippi State Medical Association, has been appointed superintendent of the Mississippi State Hospital, Jackson, succeeding Dr Charles D Mitchell who has held the position for eighteen years—Dr Byron H Parsly, Como, has been appointed surgeon of the state penitentiary, succeeding the late Dr William P McDavid, Parchman—Dr Russell R Welch of the staff of the state hospital at Jackson, has been appointed superintendent of the East Mississippi Insane Hospital at Meridian, succeeding Dr Matthew J L Hove

### NEBRASKA

**Society News**—Dr Palmer Findley, Omaha, recently discussed "Irradiation in Pelvic Disorders" before the Cedar, Dakota, Dixon, Thurston and Wayne Counties Medical Society, in Wayne—The Southwestern Nebraska Medical Society was addressed at McCook, April 12, by Dr Leon S McGoogan, Omaha, on "The Induction of Labor"—Dr Andrew D Brown, Central City, discussed diarrheas of children before the Hall-Merrick and Howard Counties Medical Society at Grand Island in April

### NEW JERSEY

**Art and Hobby Exhibit**—At the annual session of the Medical Society of the State of New Jersey in Atlantic City, June 5-7, an exhibit of original works of art or collections made by members or their families was presented. Entries included photographic studies by Drs J Corwin Mabey, Montclair, William L Vroom, Ridgewood, William C Wescott, Atlantic City, and Lewis H Loeser, Newark, oil paintings by Drs Frederic J Hughes, Plainfield, and Hiliard L Lockwood, Jersey City, four busts by Dr Siegfried Husserl, Newark

**Dr Ill Honored**—The Academy of Medicine of Northern New Jersey held a special meeting in Newark, May 17, to celebrate the eightieth birthday of Dr Edward J Ill, Newark. Dr John F Hagerty, Newark, past president of the academy and of the Medical Society of New Jersey, presided and Drs George W Kosmak and George Gray Ward, New York, paid tribute to Dr Ill in formal addresses. A bust of Dr Ill, made by Dr Siegfried Husserl, Newark, was presented to the academy and accepted by Dr Arthur W Bingham, East Orange. Dr Frederic J Quigley, Union City, president of the Medical Society of New Jersey, brought greetings from the state society, and Dr Edward W Sprague, Newark, president of the Essex County Medical Society, greetings from that organization. Dr Ill is a past president of the state society and of the American Association of Obstetricians and Gynecologists and was the first president of the Academy of Medicine of Northern New Jersey

### NEW YORK

**Hospital News**—Albany Hospital has recently renovated its psychiatric wards and rededicated that section of the hospital as the Mosher Memorial, in memory of the late Dr Jesse Montgomery Mosher, who was the first physician of the hospital—Brig Gen Frank T Hines, Veterans' Administrator, made the principal address at the dedication of the new Veterans' Administration Facility at Batavia, June 23

### New York City

**Dr Rappleye Appointed Dean of Dental School**—Dr Willard Cole Rappleye, dean of Columbia University College of Physicians and Surgeons, has been appointed dean also of the School of Dental and Oral Surgery, effective July 1. He has been acting dean of the dental school during the absence on leave of Dr Alfred Owre, who has now resigned

**Dinner in Honor of Dr Ashford**—A dinner in honor of Dr Bailey K Ashford, recently retired as a colonel of the Medical Corps, U S Army, was held at the Harvard Club, June 27, in recognition of his contributions to tropical medicine. Dr Ashford was reported to be ill at his home in Puerto Rico. He is professor of tropical medicine and mycology at Columbia University collaborating with the School of Tropical Medicine of Puerto Rico. A bust of Dr Ashford was recently unveiled at the school in San Juan. The dinner was arranged by New York physicians and officials of the Pan American Medical Association on the occasion of the publication of Dr Ashford's autobiography, "A Soldier in Science"

### NORTH CAROLINA

**Personal**—Dr Merle D Bonner, Jamestown, has been appointed superintendent and medical director of the Guilford County Sanatorium to succeed the late Dr Joseph L Spruill—Dr Zack P Mitchell, Weldon, has been elected health officer of Vance County, the county has been without a health official since the resignation of Dr Crete N Sisk, Henderson, in the spring

**Society News**—Dr Robert W McKay, Charlotte, among others, spoke before the Guilford County Medical Society at High Point, April 5, on pyelitis—At a meeting of the Fifth District Medical Society in Sanford, April 19, speakers included Drs Wilburt C Davison, Durham, on pediatric therapeutics, Adlai S Oliver, Raleigh, newer conception of the female cycle, and Philander C Riley, Fort Bragg, common skin conditions—The Buncombe County Medical Society was addressed in Asheville, May 7, among others, by Dr John A Watkins on cesarean section—The Mecklenburg County Medical Society was addressed in Charlotte, May 15, by Drs John S Gaul on fracture of the spine, Roy B McKnight, intrathoracic goiter, and Edward J Wannamaker Jr, Charlotte, nephritis—Drs Rives W Taylor and Samuel M Carrington, Oxford, addressed the Granville County Medical Society, Oxford, April 28, on "Diarrheal Diseases in Children" and "Appendicitis in Children," respectively—Drs Edward W Phifer, Morganton, and Abner M Cornwell, Lincolnton, addressed the Catawba Valley Medical Society, Morganton, May 8, on "Repair of Fractures" and "Fractures of the Upper Extremities," respectively

### PENNSYLVANIA

**Fifty Years in Practice**—Dr Samuel P Glover, Altoona, was the guest of honor at a testimonial dinner given by his medical and dental friends at the Blairmont Country Club, April 19. Dr Joseph D Findley acted as toastmaster and Dr Olin G A Barker, Johnstown, was the principal speaker. Dr Glover was graduated from the University of Pennsylvania School of Medicine in 1884 and spent five years teaching at the American College in Beirut, Syria, before settling in Altoona to practice. He is the senior member of the medical staff of Altoona Hospital

**Society News**—Dr John Stewart Rodman, Philadelphia, addressed the Bucks County Medical Society, Bristol, May 9, on "Indigestion—Its Surgical Significance"—Dr Adrian S Taylor, Clifton Springs, N Y, addressed the Lycoming County Medical Society, Williamsport, June 8, on "Trifacial Neuralgia"—Dr Henry T Price, Pittsburgh, was the speaker at a meeting of the Blair County Medical Society, Altoona, in April, on "Adolescent Health"—Dr Moses Behrend, Philadelphia, president-elect, Medical Society of the State of Pennsylvania, discussed the society's policy for 1935 on workmen's compensation legislation at a meeting of the Erie County Medical Society, Erie, June 11, Dr Harold A Miller, Pittsburgh, state director of emergency medical relief, discussed "Possibilities of State Medicine in Our Present Situation"—Dr James R Smith, Erie, was elected president of the Pennsylvania Public Health Association at its annual session in Philadelphia, May 22-23

### Philadelphia

**Society News**—Dr Leonard G Rowntree, among others, addressed the Philadelphia Pediatric Society, June 12, on "Demonstration of Results on Nutrition and Growth of Rats by Thymus Feeding"—Drs Frederick S Schofield and George L Weinstein among others, addressed the Philadelphia Urological Society, May 28, on "The Friedman Test in Testicular Tumors"—The library of the Philadelphia County Medical Society added ninety-six books and fourteen journals during the fiscal year ended May 1. These bring the number of books in the library to 3,106 and the number of journals to 69. A total of 2,345 persons used the library during the year, according to the annual report

**University News**—Prizes were recently awarded to several students at the University of Pennsylvania School of Medicine, for papers on research projects. The Mary Ellis Bell prize, a gold medal and \$25, went to Maurice S Sackey for a paper on "Absorption of Bilirubin from the Small Intestine", the John C Clarke Prize, a gold key and \$25, to Joseph L Hollander, Milton Mazer and Isadore S Epstein, for a joint paper on "Effect of Total Gastrectomy on the Blood Picture of the Cat as Bearing on the Castle Hypothesis of Pernicious Anemia," and the Grayhe Simpson Priestly Prize of \$10 to Gabriel A Schwarz, Hazelton, for a paper on "Formation of the Nissl Substance—An Experimental Study." Dr Isidor S Ravdin made the presentations at a meeting of the Undergraduate Medical Association in April

## RHODE ISLAND

**Fiske Prize Awarded**—Drs Charles O Cooke and James Murray Beardsley, Providence, received jointly the annual Fiske Fund Prize of the Rhode Island Medical Society, for their essay on "Appendicitis Its Diagnosis, Treatment and End Results." The prize, which this year amounted to \$200, was established about 100 years ago by Caleb Fiske, to encourage original work on the part of members of the society, of which he was one of the early presidents.

## SOUTH CAROLINA

**Faculty Changes**—At the annual commencement of the Medical College of South Carolina, Charleston, June 6, the following faculty elections and changes were announced, among others

Dr Archibald E Baker emeritus professor of gynecology  
Dr Hillyer Rudisill Jr professor of roentgenology  
Dr Joseph Sumter Rhame associate professor of surgery  
Dr F Adelbert Hoshall assistant professor of orthopedics

The Ravenel award, a silver cup, was given to Dr William Townsend Barron Jr of the graduating class for his essay on "Selective Sterilization." This award was established by Dr Mazzyk P Ravenel, now of Columbia, Mo., in memory of members of the Ravenel family who have contributed to medicine and science in South Carolina. James C Kinard LL.D., president of Newberry College, Newberry, made the address to the graduating class.

## TENNESSEE

**New Advisory Council Appointed**—Governor McAlister recently appointed a new state council of public health to act in an advisory capacity to the state department of health. At the first meeting Dr John M Lee and Oren A Oliver DDS, Nashville, were elected president and vice president, respectively. Other members are Drs Ernest M Fuqua, Pulaski Claude P Fox Sr, Greenville William K Vance Jr Bristol, John R Thompson Jr Jackson, and John C Ayres, Memphis. The Tennessee Federated Women's Clubs and Parent Teacher Association is also represented on the council and a pharmacist member is to be appointed. Medical members of the council were chosen from a list recommended to the governor by the house of delegates of the Tennessee State Medical Association.

**Society News**—Speakers at the annual meeting of the Upper Cumberland Medical Society at Red Boiling Springs, June 6-7 included Drs George R Livermore Memphis on "Evolution of Prostatic Resection," James B E Neil, Knoxville "Use of High Frequency Currents for the Relief of Prostatic Obstruction," Carl R Crutchfield Nashville "Cure of Inguinal Hernia," George A Hendon Louisville, Ky, "Treatment of Peptic Ulcer," and Carl C Howard, Glasgow, Ky, "Cause of Death from Emboli."—Dr Thomas P Sprunt, Baltimore addressed the Sullivan-Johnson Counties Medical Society Bristol June 5, on "Common Types of Chronic Arthritis."—Drs Raymond M Price, Sweetwater, and Spencer B McClary, Etowah among others addressed a meeting of the Five County Medical Society (McMinn Monroe Loudon, Roane and Blount counties) at Athens May 25, on "Surgical Indications and Treatment of Gallbladder Disease" and "Diagnosis and Treatment of Peptic Ulcer," respectively.—Dr Charles C Stockard, Lawrenceburg among others, addressed the Hardin-Lawrence-Lewis-Perry-Wayne Counties Medical Society in Linden May 25, on postpartum hemorrhage.

## VIRGINIA

**University News**—Dr Rudolf B Teusler director of St Luke's International Medical Center Tokyo, Japan received the honorary degree of doctor of science at the annual commencement of the Medical College of Virginia Richmond May 29. Dr Teusler is an alumnus. There were ninety-seven graduates in medicine.

**Academy Approves Report on Hospital Insurance**—The Richmond Academy of Medicine recently approved a report of its committee on economics recommending that the academy formulate plans for group hospital insurance. The committee was instructed to prepare plans for approval of the academy, with due regard to certain safeguards enumerated in the report and to economic soundness.

**Personal**—Dr Oscar Swineford Jr instructor in medicine University of Virginia Department of Medicine University was awarded the John Horsley Memorial Prize at the annual meeting of Sigma Xi in April for a paper on "Specific Control of Experimental Serum Reactions." The prize awarded every two years by a committee of the medical faculty of the university was established by Dr John Shelton Horsley

Richmond, in 1925 in memory of his father. The "President and Visitors' Prize" was awarded for the second year in succession to Carl Caskey Spicdel, Ph.D., for a paper on "Studies of Living Nerves."

## WISCONSIN

**Personal**—Dr William T Clark, Janesville, has been appointed adviser on medical aspects of the joint federal and state relief department.—Dr Henry F Hoesley was elected mayor of Shullsburg in April.

**Survey of Hospital Occupancy**—Wisconsin hospitals operated at an average of 45 per cent of their bed capacity during 1933, as compared with 65 per cent in 1930, according to an economic survey recently made by the Wisconsin Hospital Association. The survey showed that the number of obstetric cases declined sharply in the three year period 1930-1933. Hospitals with less than fifty beds reported a decline from 83 in 1930 to 43 in 1933, those with between fifty and 100 beds from 225 to 126, and those with more than 100 beds from 442 to 352. Free work practically doubled in the largest and smallest hospitals and in the middle group it increased from 39 per cent in 1930 to 199 per cent in 1933. The data indicated the effect of the Federal Emergency Relief Administration's omission of hospitalization from the care provided for the indigent, according to the report. All hospitals reported drastic economies and rates have been generally reduced. Several hospitals have instituted flat rates for obstetric cases.

## GENERAL

**Bequests and Donations**—The following bequests and donations have recently been announced.

St Mary's Free Hospital for Children New York \$8,000 from the will of the late Fannie Henrietta Youngs  
Somerset Hospital Somerset N J \$10,000 by the will of the late William Morgan Savin Annandale  
Nassau Hospital Mineola L I \$30,000 by the will of the late John C Herrick Little Neck L I  
Seton Hospital and French Hospital New York \$4,000 and \$25,000 respectively and St Agnes Hospital for Crippled Children White Plains \$20,000 from the will of the late George Logan Durval  
House of Rest at Sprain Ridge Yonkers N Y \$5,000 by the will of the late Mrs Florence Macy Sutton  
Clarksdale Hospital, Clarksdale Miss \$30,000 by the will of Mrs E B Johnson

**Tuberculosis Sanatorium Directory**—The National Tuberculosis Association, 50 West Fiftieth Street, New York City, has issued a new directory of tuberculosis sanatoriums, corrected to May 1934. This directory is the tenth in a series that started in 1904. It lists 659 institutions with a total bed capacity of 86,917. It includes tuberculosis departments, pavilions, and separate wards in general hospitals. A number of institutions that previously did not admit children now report a definite number of children's beds. Several institutions have added new buildings for children. There is an increase in the number of general hospitals that admit patients suffering from tuberculosis. Information about each institution listed includes name, location, ownership, rates, types of cases admitted, limitation as to residency, person and organization in control. The price of the volume is \$1.

**Eradication of Bovine Tuberculosis**—There were 1,784 modified accredited counties practically free from bovine tuberculosis on May 1 according to the U S Department of Agriculture. This figure represents about 58 per cent of the total and includes fourteen states in which all counties were within that classification. This eradication of the disease dates from July 1923, when seventeen counties within four states were designated as the first modified accredited areas. Biennial surveys are made to determine the progress of eradication work, the first in 1922 indicated that 4 per cent of all cattle in the country were tuberculous, while in 1934 the corresponding percentage was only 11. The fourteen states in which all the counties are almost free from bovine tuberculosis are North Carolina Maine Michigan Indiana, Wisconsin, Ohio Idaho, North Dakota Nevada New Hampshire, Utah, Kentucky, West Virginia and Washington.

**Medicine at Science Meeting**—The American Association for the Advancement of Science met in Berkeley, Calif., June 18-23. The section on medicine held four sessions, two of which were given over to a consideration of the field of endocrinology, while two dealt with aspects of hygiene and parasitology. According to *Science* the first session was devoted to a symposium on general phases of the endocrine problem under the general title of "A Survey and Evaluation of the Present Status of Endocrine Investigations." Speakers were Dr Eugene M K Geiling, associate professor of pharmacology, Johns Hopkins University School of Medicine, Baltimore, Vin

cent du Vignier, Ph.D. professor of biochemistry, George Washington University School of Medicine Washington, D. C., and James M. Luck, Ph.D., assistant professor of biochemistry, Stanford University Calif. Speakers for the remainder of the program were not published. Meeting conjointly with Section N was the Pacific Coast branch of the Society for Experimental Biology and Medicine.

**Grants by National Research Council**—The committee on grants in aid of the National Research Council has announced the following grants in the field of the medical sciences:

- Dr. Joseph D. Aronson, assistant professor of bacteriology, Henry Phipps Institute of the University of Pennsylvania Philadelphia: mutual effect of tuberculosis and syphilis in experimental animals.
- Dr. Henry G. Barbour, associate professor of pharmacology and toxicology, Yale University School of Medicine New Haven: Conn.: relation of the pituitary gland to water shifting reflexes in primates.
- Detlev W. Bronk, Ph.D. professor of biophysics, University of Pennsylvania School of Medicine Philadelphia: properties and functions of the sympathetic ganglions.
- Dr. Samuel J. Crowe, adjunct professor of laryngology and otology, Johns Hopkins University School of Medicine Baltimore: physiology of the middle ear.
- Dr. John A. E. Lyster, professor of physiology, University of Wisconsin Medical School: study on the electrical field around the contracting heart and skeletal muscle and related phenomena.
- Dr. Eugene M. K. Ceiling, associate professor of pharmacology and experimental therapeutics, Johns Hopkins University School of Medicine: histologic and pharmacologic study of pituitary glands of whales, porpoises and seals.
- Dr. Arthur Crollman, associate professor of pharmacology and experimental therapeutics, Johns Hopkins University School of Medicine: chemical study of the supragenital cortical hormone.
- Dr. Harold E. Himwich, associate professor of physiology, Yale University School of Medicine: interrelated aspects of carbohydrate metabolism.
- Dr. Richard U. Light, research assistant in surgery, Yale University School of Medicine: new apparatus for investigation of neurologic functions.
- Dr. Frank A. McJunkin, professor and head of the department of pathology, bacteriology and preventive medicine, Loyola University School of Medicine Chicago: extraction and purification of agents that inhibit mitotic proliferation in the kidney.
- Dr. George C. Shattuck, assistant professor of tropical medicine, Harvard University Medical School: effects of heat.
- William F. Windle, Ph.D. associate professor of anatomy, Northwestern University Medical School Chicago: development of behavior in the embryo correlated with the development of intrinsic structure of the nervous system.

Further grants will be considered in the fall; the council announces. Application should be filed on blanks which will be furnished by the secretary of the committee before October 15. Action will be taken about the end of December.

**Society News**—At the annual session of the American Association for the Study of Gout, Dr. Allen Graham Cleveland, was installed as president. Dr. Julius R. Yung, Terre Haute, was chosen president elect and Dr. William B. Mosser, Kane, Pa., corresponding secretary and Dr. Frank B. Dorsey, Jr., Keokuk, Iowa, recording secretary. The next annual session will be held at Salt Lake City.—Dr. Clarence O. Cheney, New York, was chosen president elect of the American Psychiatric Association at its annual meeting, May 30, and Dr. Charles F. Williams, Columbia, S. C., was installed as president. Dr. William C. Sandy, Harrisburg, Pa., was reelected secretary. The next annual meeting will be held at Washington, D. C.—Dr. DeForest P. Willard, Philadelphia, was installed as president of the American Orthopedic Association at its annual meeting, June 9. Dr. Frederick J. Gaenslen, Milwaukee, was named president-elect, and Dr. Ralph K. Ghormley, Rochester, Minn., reelected secretary. The next annual session will be held at Philadelphia.—Dr. Colin K. Russel, Montreal, Canada, was elected president of the American Neurological Association at its meeting, June 5, and Dr. Henry Alsop Riley, 117 East Seventy-Second Street, New York, reelected secretary. The next annual meeting will be held at Montreal.—At a meeting of the American Laryngological Association, June 9, Dr. Dunbar Roy, Atlanta, Ga., was named president and Dr. William V. Mullin, Cleveland, was reelected secretary.—Dr. Charles M. Williams, New York, was selected president of the American Dermatological Association at its annual session, June 8, and Dr. William H. Guy, Pittsburgh, reelected secretary.—New officers of the American Association on Mental Deficiency elected May 29, are Dr. Mary M. Wolfe, Laurelton, Pa., president; Edgar A. Doll, Ph.D., Vineland, N. J., president-elect; and Dr. Groves B. Smith, Godfrey, Ill., secretary (reelected).—Dr. Edward B. Krumpholtz, Philadelphia, was elected president of the American Association of the History of Medicine at the tenth annual session in Cleveland, June 11. Drs. Charles N. B. Camac, New York, and William S. Middleton, Madison, Wis., were elected vice presidents and Dr. Edward J. G. Beardsley, Philadelphia, secretary. Any one interested in the subject who wishes to become a member of the association is asked to communicate with Dr. Beardsley, 1919 Spruce Street, Philadelphia.

## CANADA

**Canadian Medical Association**—At the meeting of the Canadian Medical Association in Calgary, Alta., June 18-22, Dr. Jonathan C. Merkins, Montreal, was named president-elect of the association. Among guest speakers were the following:

- Dr. Alex. Cutler, Chicago: Cancer of the Breast.
- Dr. Sanford R. Gifford, Chicago: Treatment of Glaucoma. Corneal Infections.
- Dr. Ralph A. Ienton, Portland, Ore.: Recent Discoveries in Pathology of the Nasal and Anal Mucosa.
- Dr. John M. Frawley, Fresno, Calif.: Treatment of Typhoid in Children by Means of Lysed Vaccine. Prophylaxis and Treatment of Whooping Cough.
- Dr. Gordon B. New, Rochester, Minn.: Curability of Malignant Tumors of the Upper Jaw and Antrum.

The Blackader Lecture was delivered by James Craigie, research associate, Connaught Laboratories, University of Toronto, on "Some Aspects of Virus Infections, with Special Reference to Virus Diseases of Childhood." In a symposium on cancer participants were Drs. Alexander Primrose, Toronto, Earl C. Shepley, Saskatoon, William J. L. Deadman, Hamilton, and Donald C. Balfour, Rochester, Minn. A symposium on cardiovascular diseases was presented by Drs. Duncan A. L. Graham, John A. Oille, and John Hepburn, Toronto, and Cecil C. Birchard, Montreal.

## FOREIGN

**Dawson Williams Prize Awarded**—The third award of the Dawson Williams Prize, established in 1928 in memory of the late editor of the *British Medical Journal*, will be made to Dr. George F. Still, professor of diseases of children, King's College London, at the annual meeting of the British Medical Association, July 24, in Bournemouth. The prize a certificate and a check for fifty guineas, has previously been awarded to Dr. Frederick J. Poynton (1930) and the late Sir Robert Jones (1932).

**Congress on Electro-Radio-Biology**—The first International Congress of Electro-Radio-Biology will be held in Venice, September 10-15, for the study of the biologic phenomena caused by radiations. Physicists, chemists, biologists, naturalists and physicians are expected to attend. Among Americans listed on the preliminary announcement are William D. Coolidge, Ph.D., Schenectady, N. Y., Otto Glasser, Ph.D., Cleveland, and Arthur H. Compton, Ph.D., Chicago. Information may be obtained from the secretary of the congress, Dr. Giocondo Protti, Venice, Canal Grande, S. Gregorio 173.

**Medical Study Trip**—The twenty-seventh medical study trip sponsored by the mineral water and climatic resorts of France under the patronage of the minister of public health will take place during the first two weeks of September. It will be under the scientific direction of Dr. Maurice Villaret, professor of hydrology and therapeutic climatology of the Faculty of Medicine of Paris and physician of the Necker Hospital, among others. The trip will include les Gorges du Tarn, l'Aigoual, les Gorges de l'Herault, Montpellier, les Corbieres, la Montagne Noire, les Gorges de l'Aude and la Cote de Vermeil as well as all the resorts of the Languedoc, eastern section of the Pyrenees, and the republic of Andorra, breaking up at Toulouse. For information apply to Made-moiselle Machure, 138 avenue des Champs-Elysees, Paris (VIII).

## Government Services

### The Reporting of Venereal Diseases

Because of the widespread prevalence of venereal diseases, the U. S. Public Health Service is preparing a monthly morbidity report for physicians and others interested in the prevention and eradication of syphilis and gonorrhea to assist state and local boards of health in interesting individual physicians of the United States in more thorough reporting of these diseases. Surveys in representative communities throughout the United States have revealed that the monthly rate per 10,000 of population is 66 for syphilis and 102 for gonorrhea. During April, the figures for which have just been released 18,377 cases of syphilis and 10,111 of gonorrhea were reported for thirty-four states and the District of Columbia. The states not represented in these statistics include California, Pennsylvania and West Virginia, which have been reporting regularly, but for which no report had been received for the current month, Colorado, Nevada, Utah and Wyoming which do not report and Connecticut, Iowa, Montana, Ohio, Oklahoma and South Carolina which had incomplete figures. Only cases in the infectious stage are reported for Wisconsin.

#### Debate on Medical Versus Surgical Treatment of Peptic Ulcer

The Fellowship of Medicine arranges debates, in which leading authorities take part, on moot points in practice. The latest one was on the motion that, in the absence of complications, surgical intervention in cases of gastric and duodenal ulcer is unnecessary. Lord Moynihan was in the chair. Opening the debate, Dr A F Hurst said that ten years ago Lord Moynihan contended that a gastric ulcer large enough to produce a crater demonstrable by roentgen rays could be cured only by operation. But about that time Dr Hurst saw the largest gastric ulcer in his experience and treated it by medical means. The symptoms disappeared in three months and for years did not return. To be effective, medical treatment must be thorough and prolonged. Duodenal ulcer was a more difficult problem than gastric ulcer, largely because the duodenum was narrower than the stomach and slight swelling or spasm sufficed to cause obstruction. Nevertheless it was rare for an ulcer of less than ten years' duration not to heal under medical treatment. An exception was the familial type, in which the hemorrhage began early in life and gastrectomy alone was effective. Some advocated operation in order to prevent hemorrhage or perforation, but he had never seen perforation when the patient had proper medical treatment sufficiently long. In seconding the motion, Mr A E Mortimer Woolf did not think that all peptic ulcers, in the absence of complications, should necessarily be treated by medical means. In a straightforward case of ulcer without complications, he would try other methods before resorting to operation.

Dr Robert Hutchison said that he had maintained years ago that many unnecessary operations were performed for duodenal ulcer, but the results obtained by Mr James Sherren at the London Hospital had changed his views. He was astonished at Dr Hurst's claim that every uncomplicated gastric ulcer would heal under medical treatment. After five years the results remained satisfactory in only about half the cases. Patients who had been operated on could live a freer life without the rigorous restrictions of medical treatment.

Mr Herbert Patterson did not approve of duodenal intubation, which was based on unsound principles. Gastric ulcers could be healed under medical treatment, but he doubted whether this was true for well established duodenal ulcers. He opposed the motion because a large ulcer would not heal under medical treatment and a duodenal ulcer seldom or never healed. He had eleven physicians as patients who preferred medical treatment and three of them had perforations, one fatal.

Dr Walter Carr stated that sooner or later all or almost all cases of gastric, and certainly all cases of duodenal, ulcer relapsed. A second relapse should mean operation. The only alternative was severe restrictions for the rest of the patient's life. It was better to face the comparatively small risks of operation.

Lord Moynihan said that the point which needed insistence was the inefficiency of medical treatment as generally carried out. He was strongly in favor of medical measures. Of five patients consulting him for surgical treatment, three were referred back to the physician, but not infrequently some returned after medical treatment. Ulcers took long to heal, and rest in bed on a restricted diet was necessary for a considerable time. Because of the risk of perforation or hemorrhage medical treatment was more dangerous than surgical

But he rarely liked to operate until nonoperative treatment had been tried as thoroughly as possible. In contradiction to Dr Hurst, he had seen many deaths from hemorrhage or perforation while the patient was under medical treatment. The voting was for motion, 70, against, 73.

#### Antimony Poisoning from Enamel Ware

The Ministry of Health has repeated its warning that the use of cheap enamel ware may cause antimony poisoning. The substance normally used as an opacifier in enamel ware is tin oxide. In recent years this has been replaced to some extent by the cheaper oxides of antimony. Antimony trioxide dissolves in tartaric and other organic acids. The solution is a violent emetic and may cause death. When soft enamels are brought in contact with lemonade, whether artificial or made from lemons, a similar solution may be produced, and outbreaks of poisoning have so occurred. The use of antimony in hollow ware might be brought under control by the marking of enameled goods or allowing only the pentoxide or its compounds to be used, but it is suggested that prohibition would be better.

#### The Assistance of Foreign Scientists

The Academic Assistance Council, formed to assist scholars and scientists who were victims of the German persecution, has enabled 180 displaced teachers from German universities to continue their work. The aim of the council has been widened to the general defense of academic freedom and the helping of those of any nationality who on grounds of religion, race or political opinion are prevented from working in their own country. There are Russian and Italian emigres in a similar position to the German. In a letter to the *Times*, Lord Rutherford, who by his fundamental work on the atom has attained the leading position in British science and presides over the council, describes the number of refugees as "tragically swollen by the expulsion from Germany of persons possessing pacifist or international convictions or lacking that strangest qualification for the life of scholarship, 'Aryan genealogies'." To incorporate the services of these wandering scholars in the other universities of the world is more difficult today than in the Middle Ages, when the "communities of learners" were less hampered by administrative formalities, restrictive endowments and nationalist tendencies. Medieval scholars could migrate to other districts, and the "universitas" moved with them, the same catholicity of spirit has been fortified in the present crisis in both ancient and modern universities. The universities of Great Britain have responded generously to the council's suggestion of inviting displaced scholars to work as research guests. London University has received sixty seven. Cambridge has not only given hospitality to thirty one but has contributed over \$5,000 to the council's funds, Oxford has welcomed seventeen. Manchester University has invited sixteen and raised a special fund for their support. Almost all other universities and university colleges in Great Britain have opened their common-rooms, libraries and laboratories to temporary research guests and several have raised funds. The British university teachers have contributed liberally and the members of the staff of the London School of Economics have taxed themselves voluntarily for a period of three years. But there is urgent need of funds. Almost all that has been collected has been expended in maintenance grants, at the rate of \$900 per annum for a single person and \$1,250 for a married one. The council has received reports of the excellent results of the collaboration in research of English and foreign colleagues. Several notable discoveries have been made. The council is conducting a world-wide survey to discover openings in which the services of our colleagues can be used. The reorganization of the University of Istanbul has provided posts for more than thirty. The formation of the "University in Exile" in New

York and projects in Russia, Persia and Brazil for creation of university institutions show that group settlement is possible. In Germany, 1,202 university teachers have been displaced. So far only 389 are known to have found even temporary places elsewhere, and of these 178 have found academic refuge in Great Britain. The council is not merely a relief organization, in one of the greatest crises in the history of universities it is determined to preserve respect for the basic traditions of academic freedom and the integrity of science.

#### Repeal of the Duty on Insulin

The removal of the tax on imported insulin almost as soon as it was imposed was reported in a preceding letter. It provoked an outburst in the house of commons from a protectionist, who said that it was inappropriate that on the day it was announced that Dr F. G. Banting the discoverer of insulin, was honored with a knighthood its manufacture should be 'handed over to a foreign monopoly.' The 33 per cent duty had not been followed by any rise in the price of insulin. He omitted to state that the abolition of the duty had been followed by a fall in the price of insulin or that it was behind tariff walls that monopolies flourished most. Mr Chamberlain, chancellor of the exchequer, said that the imposition of the duty was 'a kind of accident,' which the manufacturers asked for. It was opposed by the board of trade and taken before the tribunal appointed to decide on duties. The government repealed the duty because of representations that persons with diabetes felt that the price of insulin was higher than it would have been but for the duty. To a considerable number of people, diabetes was a matter of life and death. He admitted that the price had fallen since the duty had been repealed but being an ardent protectionist, he failed to see how this had exploded the pretense that the higher price was only a 'feeling' on the part of diabetic patients.

#### French Congress of Gynecology

The third *Congres français de gynécologie* was held in Paris, May 5-9, under the chairmanship of Prof. André Binet of Nancy. Among the foreign official delegates present were Blair Bell of London, Leopold Mayer of Brussels, Koenig of Geneva, and Daniel of Bucharest. Professor Roussy, dean of the *Faculté de médecine de Paris*, opened the session with an address in which he endeavored to define the physical and psychic personality of woman. He pointed out that, in the physical sense, woman constitutes a harmony of endocrine influences. He emphasized the social role of woman and cited the following utterance of Pende of Genes: "Every decadence of a civilization is heralded by the decadence of woman and by the predominance of egoistic instincts, which are more or less antimaternal." The address of Professor Binet dealt likewise with the relations of gynecology to present-day sociology. He discussed the beneficial and harmful influences of sport activities—depending on their choice and management—on the physical development of woman. He condemned the spirit of competition, which induces women to try to establish absurd records and which removes them from their natural sphere, the home, and tends to make some modern women 'beings of uncertain sex,' poorly adapted to the duties of motherhood. Taking into account the constitution of young women the physician should prohibit too violent sports, such as skiing and motorcycle riding. The chief topic was "anatomic and physiologic aspects of the ovary." The study was divided among six speakers. The paper of Dr. Leopold Lévi (recently deceased) on the "Mutual Relations Between the Ovary and the Thyroid Body" was presented by Mr. Roland Leven and Miles Hirsch

and Vouaux. The paper threw new light on the relations between hypofunctioning and hyperfunctioning of the ovary in relation to exophthalmic goiter. Anovarianism due to ovariectomy, and congenital or acquired hypo-ovarianism and dysovarianism may cause symptoms of exophthalmic goiter. Anovarianism and ovarian insufficiency, as these are manifested during the menopause or following repeated pregnancies, may cause hypothyroidism or even myxedema to appear. Menstruation, a period of hyperovarianism, is often accompanied by symptoms of hyperthyroidism—more rarely by symptoms of hypothyroidism, and sometimes by disturbances due to thyroid instability. Whatever the thyroid reactions secondary to ovarian disturbances may be, they are always conditioned by the evolution of the ovarian disturbances. The more or less rapid pathologic evolution of the ovary will necessitate different efforts at adaptation on the part of the organism and the endocrine system. Of still greater importance appears to be the previous state of the thyroid gland. Dependent on its previous functional trend, the deviation will be in the direction of hypothyroidism or hyperthyroidism. A previous state of thyroid instability makes more easy the reaction in the direction of hyperthyroidism. The thyroid disturbance may react on the utero-ovarian apparatus, causing thyro-ovarian syndromes. Hyperthyroidism and exophthalmic goiter may inhibit ovarian functions or induce genital atrophy. When there is a parallelism—hyperthyroidism and hyperovarianism—it is more a question of a constitutional state than a pathologic state. The thyroid insufficiency may be accompanied by symptoms of hyperovarianism (excessive menses). Often there is a parallelism between thyroid insufficiency and ovarian insufficiency. The syndrome of thyroid instability is associated more commonly with symptoms of hypo-ovarianism. In other cases, one may observe symptoms of thyroid instability and of ovarian instability combined. In all the cases in which there is a predominance of signs of hypothyroidism, their significance is demonstrated by the influence of thyroid treatment on the functioning of the ovary after failure of ovarian treatment. A study of the ovariothyroid and thyro-ovarian syndromes throws light on various ideas: (1) the extragonadal influences, that is, endocrine and thyroid influences—particularly on the physiopathology of menstruation, (2) the rapid passage of a poorly developed glandular apparatus from infantilism to senilism, such as appears in the syndrome "late puberty and early menopause," and (3) the preponderant influence of the thyroid gland on the syndrome of premature aging of the organism.

#### A Study of Acute Articular Rheumatism

The eleventh session of the *Assemblée des praticiens* was presided over by Professor Olmer of Marseilles. The chief topic was "The Present Status of Acute Rheumatism," which had been discussed in advance in the departmental medical societies. The meeting in Paris of all the delegates of these societies made possible a comprehensive synthesis of their conclusions. This sort of medical convention, which is held quarterly and which brings together the professors and the practitioners of even the most remote rural districts, always presents a high degree of interest. The conclusions reached by the discussion follow. Acute articular rheumatism is much more rarely observed than formerly, doubtless owing to the adoption of treatment with sodium salicylate, whereas rheumatism that is chronic from the start is increasing. Acute rheumatism reaches its highest point at the close of winter and the beginning of spring, with recrudescences during the summer and sometimes during the fall. Series of cases have been studied particularly in the young soldiers of the French army. An epidemic often affects a contingent of the army, although no cases appear in the homes of the vicinity. Acute rheumatism has been found hereditary through several generations.

But there are usually intervals between the succession of familial cases, so that the idea of habitual contagion is not well founded. Acute rheumatism has shown of late a marked decrease. The serious types especially are less often observed. There are, however, many attenuated articular forms, abortive types presenting incipient cardiac lesions. Acute articular rheumatism appears to be the arthropathic type of a disease that with its cardiac localization, is much more than articular. The abnormal localizations are much more frequent than the cerebral type, which is exceptional. The most common associated disorders are chorea and tuberculosis. Without assuming the tuberculous nature of Bouillaud's disease, the clinician sees typical cases of this disease in tuberculous patients and finds salicylate medication effective. The good effects of sodium salicylate are universally recognized. If used promptly and energetically for an extended period, without omission of regular doses through the night (for rheumatism never sleeps!), salicylate may accomplish excellent results. In a private clientele doses of from 8 to 12 Gm may be regarded as maximal and sufficient, although much lower than are used in the hospital services, and particularly in military hospitals. As regards prophylaxis, the practitioners, considering angina as the most frequent premonitory event advised salicylate medication, at least in rheumatic patients recognized or insufficiently treated. Victims of occupations that they did not know were contraindicated for persons in their condition show the need of spreading useful ideas on the subject as is done by the Ligue du rhumatisme. Before the general discussion was opened numerous communications were presented and gave rise to differences of opinion, particularly on the question of heredity and contagion in acute rheumatism, cardiac localization preceding articular localization the role of scarlet fever, and the association of tuberculosis and acute rheumatism.

#### The Pasteur Institute

The death of Prof. Emile Roux, director of the Institut Pasteur, and of Professor Calmette, assistant director, which occurred only a few weeks apart, left that famous scientific institution without a head. After three months of deliberation, the Conseil d'administration de l'Institut has chosen Dr. Louis Martin as director. Dr. Martin is the oldest surviving collaborator of Pasteur. In collaboration with Dr. Roux he discovered antidiphtheritic serum at the same time as Behring. Mr. Felix Ramon, head of the Annexe de Garches, and inventor of diphtheria anatoxin, has been appointed assistant director.

#### BERLIN

May 14, 1934

#### The Number of Living Births in Europe

In 1933 the number of living births in Europe showed a further decline. According to a preliminary report, the greatest decrease occurred in the East European countries, which still have a comparatively high birth rate. In Rumania, in the first six months of 1933 there were 42,000 (12.4 per cent), in Poland, 35,400 (7.5 per cent), and in Czechoslovakia, 12,800 (7.9 per cent) fewer children born than in the first half of 1932. In Hungary the number of births for the first nine months of 1933 was 8.8 per cent, and in Lithuania 7.7 per cent lower than for the corresponding period of the previous year. The decline in the number of births was very marked in Austria (6.2 per cent) and in Bulgaria (6.0 per cent). In France which has had, since the war, a comparatively steady birth rate 33,110 or 6.0 per cent, fewer living births were recorded for the first nine months of 1933 than in the corresponding months of 1932, whereas the decline in births for the previous year in France was less than 8,000. For the period of nine months Great Britain reports a decrease in the number

of living births amounting to 26,450, or 4.7 per cent, and the Netherlands a decline of 4.4 per cent. In the German Reich however, in consequence of the slight increase of births in the third quarter, the total number of living births for the corresponding nine-month period was only 21,100, or 2.8 per cent fewer than for the same period of the previous year. Thus, in 1933, the German Reich stood, for the first time in many years, among the countries with a relatively slight decline in the birth rate, by the side of Spain, Portugal, Switzerland and Italy.

#### The Social Significance of Schizophrenia

According to an address by Wetzel before the Stuttgarter Aerztliches Verein, schizophrenia is the most frequent psychosis. In 1929, 69 per cent of the inmates of psychopathic hospitals in Wurttemberg (more than 3,000) were schizophrenic, two thirds of them being cared for at the expense of the department of public welfare. The average duration of hospitalization for schizophrenic patients is eight and one half years. This signifies more than 25,500 years of treatment for the whole group, which reveals the vast importance of the disease from the social point of view. Only a certain percentage of schizophrenic patients are in hospitals, since many do not require institutional treatment. The records of the public welfare department show that many asocial persons (beggars, vagrants, prostitutes and criminals), while not necessarily active in crime, are schizophrenic patients of long standing. A moralizing attitude often prevents the correct psychiatric understanding of these patients. The welfare services must therefore recognize the limits of their capacity and authority, since otherwise public and private funds will be wasted on useless courses of treatment. Otherwise the usual (though false) diagnosis of an 'unruly psychopath' will be made, whereas in many cases it is a question of unrecognized schizophrenia. The outstanding essential manifestation in schizophrenia is the unaccountability characterizing a patient's conduct. Between onset and internment lies often a violent deed due to an explosion resulting from excessive tension (suicide, pathologic whims that may have dangerous results).

The attitude of society toward schizophrenic subjects is characterized chiefly by two points of view: the desire to bring them under welfare treatment and the recognition of the need of defending itself against sudden violent attacks. Early dismissal from an institution constitutes a menace to the population, from a hereditary point of view. The recent application of sterilization to such patients with hereditary defects is therefore welcome legislation. The central problem in the application of welfare principles to the previously interned patient who is stamped as a schizophrenic subject is the providing of suitable employment. In the institution the work takes on a therapeutic character but, at the same time, it serves as a contribution of the patient toward the support of the institution, through a saving of personnel. So long as the schizophrenic subject is able to work he need not be reckoned among the invalidity class. It cannot be expected however, that he will fully readapt himself to the ways of society.

#### Treatment of Psoriasis with Low Fat Diet

Grutz addressed recently the Leipzig Medical Society on 'The Psoriasis Problem in the Light of Etiologic Research and Clinicodietetic Observations.' In the pathogenesis of psoriasis hereditary influence plays an important part. Nothing definite is known in regard to the cause. Never researches on the genesis and on new methods of treatment are based on histologic observations of Grutz on the skin of a patient who had simultaneously diabetes, psoriasis and xanthomatosis, with a permanent hyperlipoidemia and hypercholesterolemia. In the psoriatic skin areas of the patient, by means of fat staining

he found an invasion of lipid substances that were stored in the psoriatic scaly deposits. Grütz explained this observation as a manifestation of the existing fat metabolism disturbance of lipoidosis or xanthomatosis, or as a revelation of a process that may occur regularly in psoriasis, but usually cannot be demonstrated because it is not sufficiently pronounced.

The question arose as to whether it might be possible in psoriasis to demonstrate, by a functional test of fat metabolism, similar disturbances to those that have been diagnosed in xanthomatosis and other lipoidoses. With Professor Burger of Bonn a large number of psoriatic patients were subjected to the Bürger functional test and to the analysis of their fat metabolism. The tests revealed in psoriatic patients disturbances in the lipid economy that represented on the average, about a 40 per cent increase over normal of the total blood serum fat and showed an increase of the total cholesterol and the phosphatids. Furthermore restoration of the fat metabolism to normal took a different course in psoriatic patients than in normal persons. Grütz regards these disturbances of fat metabolism as just as fundamental for the pathogenesis of psoriasis as the corresponding disturbances of the lipid economy have become for the conception of xanthomatosis. It is possible that in psoriasis there is an excess supply of the physiologic fats needed for the functioning of the skin. These are given off, in quantities too large to be utilized by the blood through the capillary system of the skin pass over into the epidermis, and there produce psoriasis. Another possibility is that the lipoids constantly transported to the epidermis reach the skin in such proportions as constitute an unphysiologic mixture. In both instances the psoriasis might be explained as inflammatory reactions toward a pathologic amount of lipid substances. This conception is opposed to Kerckhoff's view and makes unnecessary his theories in regard to a disturbed chemism of the epidermis in psoriasis.

In the Wuppertal-Elberfeld dermatologic department Gotz undertook to treat psoriasis by means of a diet poor in fats. In a number of grave cases these trials were successful so that the severest types of psoriasis were relieved by this fat-poor diet. The skin of the patients becoming absolutely clear of all lesions. The fundamental condition is the consistent application of the fat-poor diet, which permits the use of only 20 Gm of fat, at the most, for adults and 10 Gm for children (including the fat used in the preparation of the food for the table), over longer periods, if necessary, several months. In juveniles the good results are more quickly in evidence than in adults—often after from two to three weeks. The scales become loosened and the inflammatory infiltrates regress. In adults these results are not effected until after the lapse of six weeks or even longer and in stubborn cases from six to eight months are required for a complete cure. Often (particularly in psoriasis in the eruptive stage or in cases previously treated with roentgen rays) it proves impossible to check the disease manifestations by means of the fat poor diet. In a few instances the foci even become somewhat enlarged.

The psoriasis returns if the fat-poor diet is neglected. A distinct advance of the dietetic treatment is that the troublesome ointment treatment is done away with and the patients are spared the disappointments of roentgen treatment. A disadvantage of the new method is that it requires long periods of application, and can be used ambulant only under favorable home surroundings. In grave cases in which the patients are unable to work, the method presupposes a prolonged stay in the hospital. Hence, the fat-poor dietetic treatment of psoriasis should be reserved primarily for the severe cases.

The high incidence of psoriasis in butchers and in countries with a cold climate, and the retrogression of the disease during years of war with the shortage of fats find an explanation in the new conception.

### Coccygodynia

Dr Achilles de Arujo, member of the National Academy of Medicine gave a conference in which he called attention to the differential diagnosis of lumbosacral disorders of the vertebral column. Pain is constant in all these disorders and frequently dominates the clinical picture. The systematic diagnoses of lumbago, rachialgia and so on constantly mask disorders that can be identified only by means of well directed examinations. Among numerous cases at first diagnosed traumatic lumbago the author succeeded in identifying such disturbances of the lumbosacral segment as spina bifida occulta, sacralization of the fifth lumbar vertebra, spondylolysis, movable sacrum and lumbosacral arthritis. One case merits especial mention. A woman, aged 21, born prematurely, slipped and landed on her buttocks so violently that for one hour she lost the use of the lower limbs. She continued to suffer for days from severe pain in the sacrococcygeal region with irradiations in the lower limbs, which practically prevented her from walking. In May 1932 the patient was examined by the author, who made a diagnosis of sacrum acutum, anterior dislocation of the coccyx and refractory coccygodynia and proposed resection of the coccyx and osteoplasty of the crista and of the lower extremity of the sacrum. He obtained excellent results. The patient was in excellent condition when seen recently by the author. The treatment of coccygodynia, according to the author is essentially surgical.

### The Lombroso Prize

The Lombroso prize, which is annually given in Italy for the best work on criminal anthropology, until now has been given only to three scientists of universal reputation, Profs Ruiz Funes of the University of Madrid, Isreal Castellanos, director of the office of identification of Cuba, and Benigno di Tullio of the Faculty of Medicine and police school of Rome. The work for which the prize for 1933 was awarded to Brazil was elaborated at the institute of police identification of Rio de Janeiro by its director, Dr Leonidio Ribeiro and his assistant Dr Berardimel. It consists of three parts, in the first of which is described the organization of the institution. The second part shows the installations of the newly created laboratories, one of police technic and one of criminal anthropology. The last volume includes the first thirty-three anthropometric cards of criminal Negroes made at the institute, with the observations made on the biotype of each one of them. Several foreign specialists competed for the prize.

### Organization of an Order of Physicians

The Paulista Association of Medicine held a general meeting, March 9, to discuss the organization of the Order of Physicians or of the Federation of Medical Associations. The following objects of the federation were submitted for approval. To promote the compulsory federation of all medical societies in the country. All physicians who do not belong to any society must be inscribed directly in the federation. The federation will aim (a) to promote the study and adoption of a Brazilian code of deontology (b) to fight for the nationalization of medicine in other words, for the right to practice by native Brazilians only or by those who being naturalized take the whole medical course in one of the faculties of the country (c) to fight for penal laws which would make effective the action of police in the campaign against quackery (d) to fight for the creation of a private tribunal on matters pertaining to public health.

These propositions were widely discussed at the meeting and the project received a large majority of votes. The date for the next meeting of the association has not yet been fixed.

## Marriages

PERRY MARTIN WORKMAN, Woodruff, S C, to Miss Anne Thompson of Ware Shoals, May 24

WILLIAM VINCENT FETCHO, Jennerstown, Pa, to Miss Gertrude Gluck of Pittsburgh, June 13

HARRY LEE DENOON JR, Nassawadox, Va, to Miss Clara West Griffin of Eastville, recently

IRBY BAAXTER BALLENGER to Miss Mary Lou Jackson, both of Albuquerque, N M, May 16

EDWIN G QUATTLEBAUM JR to Miss Betty Cummings, both of Rockford, Ill, May 19

MARSHALL QUENTIN BAKER to Miss Belle Claire Good, both of Chicago, June 24

EARL R. CARLSON to Miss Ilse Schneider, both of New Rochelle, N Y, June 13

## Deaths

William Chris Finnoff Ⓢ Denver, University of Colorado School of Medicine, Denver, 1912, secretary of the Section on Ophthalmology, American Medical Association, 1923-1931, and elected chairman in 1933, member of the American Academy of Ophthalmology and Oto-Laryngology and the American Ophthalmological Society fellow of the American College of Surgeons, formerly associate professor of ophthalmology at his alma mater, served during the World War, ophthalmologist to the Colorado General, Mercey and St Luke's hospitals, aged 43, died, June 10, of heart disease

Alvah Hunt Doty Ⓢ New York, Bellevue Hospital Medical College, New York, 1878, at one time lecturer on quarantine sanitation, University and Bellevue Hospital Medical College, for many years health officer of the port of New York, medical director of the Western Union Telegraph Company, 1913-1933, during the World War member of the subcommittee on welfare work of the advisory commission of the Council of National Defense, aged 79, died, May 27, at his home in Pelham, of cerebral hemorrhage

William Temperance Dodge, Reed City, Mich, University of Michigan Medical School, Ann Arbor, 1880, member and past president of the Michigan State Medical Society, fellow of the American College of Surgeons, formerly member of the state board of registration in medicine, served during the World War, at one time mayor of Big Rapids, for many years on the staff of the Mercy Hospital, Big Rapids, aged 74, died, June 8, of cardiovascular disease and cerebral hemorrhage

John Henry Thompson, Kansas City, Mo, College of Physicians and Surgeons in the City of New York, medical department of Columbia College, 1877, member of the Missouri State Medical Association, past president of the Jackson County Medical Society, fellow of the American College of Surgeons, aged 82 on the staffs of the Kansas City General Hospital and St Mary's Hospital, where he died, April 7, of heart disease

Elmer Elsworth Liggett Ⓢ Oswego, Kan, College of Physicians and Surgeons, Keokuk, Iowa, 1884, Bellevue Hospital Medical College, New York, 1893, fellow of the American College of Surgeons, past president, and chairman of the necrology committee, Kansas Medical Society, 1920-1930, past president of the Labette County Medical Society, aged 73, died, June 3, of carcinoma of the bladder

Clarence Van Reynegom Bumsted, Newark, N J, University of Pennsylvania School of Medicine, Philadelphia, 1907, member of the Medical Society of New Jersey, on the staffs of the Lake Placid (N Y) General Hospital, Presbyterian and Babies hospitals, Newark and the Essex Mountain Sanatorium, Verona, aged 55, died, May 27, of cerebral hemorrhage

George Farrar Patton, New Orleans, University of Bonn, Germany, 1876, professor of the practice of medicine, emeritus, New Orleans Polyclinic member, 1892-1896, and secretary, 1896-1906, Louisiana State Board of Health visiting physician since 1893, and registrar since 1906, Charity Hospital, aged 81, died, April 2, in the Mercy Hospital

William Henry Righter, Topeka, Kan, Jefferson Medical College of Philadelphia, 1879, member of the Kansas Medical Society, formerly lecturer on genito urinary diseases, Kansas Medical College, Medical Department of Washburn College, Topeka, aged 81, died, April 24, of pneumonia and dilatation of the heart

John Peter Zohlen Ⓢ Sheboygan, Wis Marquette University School of Medicine, Milwaukee, 1913, fellow of the American College of Physicians, president of the Sheboygan County Medical Society, president of the Sheboygan Clinic, aged 47, died, June 2, in St Nicholas Hospital, of agranulocytosis

William Francis Cooper, Newport News, Va, Bellevue Hospital Medical College, New York, 1879, member of the Medical Society of Virginia, formerly councilman, member of the school board and health officer, aged 78, died, May 20, in the Elizabeth Buxton Hospital, of coronary thrombosis

Ernst Thum Ⓢ Bayonne, N J, University and Bellevue Hospital Medical College, New York, 1900, fellow of the American College of Surgeons, visiting surgeon to the eye, ear, nose and throat department of the Bayonne (N J) Hospital and the Christ Hospital, Jersey City, aged 55, died, May 31, in the Neurological Institute of New York

Harry Charles McCarthy Ⓢ Richland Center, Wis, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, past president and secretary of the Richland County Medical Society, served during the World War, aged 54, died, May 14, of pneumonia

William Moore Bogart, Chattanooga, Tenn, Bellevue Hospital Medical College, New York, 1889, member of the Tennessee State Medical Association, past president of the Chattanooga and Hamilton County Medical Society, aged 67, died, May 29, in the Erlanger Hospital, of erysipelas

Martha Perry, New Bedford, Mass, Woman's Medical College of Pennsylvania, Philadelphia, 1882, member of the Massachusetts Medical Society, for many years on the staff of the Morton Hospital, Taunton, aged 93, died, March 29, of hypostatic pneumonia and pleurisy

Leeming Carr, Hamilton, Ont, Canada, University of Toronto Faculty of Medicine, 1885, LRCS, LRCP, Edinburgh, L F P S, Glasgow, 1886, sheriff of Wentworth County, formerly minister without portfolio in the Ferguson Cabinet, aged 72, died suddenly, June 6

Ernest J Cather, Oakdale, La, University Medical College of Kansas City, Mo, 1903, member of the Louisiana State Medical Society, aged 56, died, May 27, in a hospital at New Orleans of adenoma of the prostate, chronic myocarditis and aneurism of the aorta

Mathias Hubert Cremer Ⓢ Red Wing, Minn, Kentucky School of Medicine, Louisville, 1891, Rush Medical College, Chicago, 1893, past president of the Goodhue County Medical Society, on the staff of St John's Hospital, aged 64, died, June 2, of heart disease

John Robert McLaughlin Ⓢ Elmira, N Y, University of Buffalo School of Medicine, 1928, served during the World War, aged 32, on the staff of St Joseph's Hospital where he died, April 22, as the result of injuries received in an automobile accident

Charles Cunningham Sr, Hammonton, N J, Jefferson Medical College of Philadelphia, 1894, formerly mayor, coroner, inspector for the board of health and school physician, aged 64, died, June 1, in the University of Pennsylvania Hospital, Philadelphia

John Vanderlaan Ⓢ Muskegon, Mich, University of Michigan Medical School, Ann Arbor, 1880, for many years member and president of the board of education, on the staff of the Hackley Hospital, aged 76, died, March 10, of cerebral hemorrhage

Olin Henry Jennings, Williamson, W Va Jefferson Medical College of Philadelphia, 1916, member of the West Virginia State Medical Association formerly member of the Public Health Council of West Virginia, aged 45, died, March 24

Albert Theodore Russell, Barnwell, S C, University of the South Medical Department, Sevanee, Tenn, 1909, member of the South Carolina Medical Association, aged 53, died, April 27, in the Baptist Hospital, Columbia, of nephritis and uremia

Milton Monroe Bauer Ⓢ Uniontown, Ohio, Long Island College Hospital, Brooklyn, 1880, past president of the Stark County Medical Society, aged 80, died, June 3, in the City Hospital Akron, of hypertrophy of the prostate and pulmonary edema

- Herbert Elwood Cary, Minneapolis University of Michigan Medical School, Ann Arbor, 1882 formerly county coroner, aged 78, died, May 28 at his summer home near Plover, of hypostatic pneumonia, uremia and cardiac asthma.
- Frank Ashmore, Santa Ana, Calif., College of Physicians and Surgeons, School of Medicine of the University of Illinois 1914, member of the California Medical Association, aged 49, died, April 30, of bronchopneumonia and pyemia.
- Elmer Floyd Coulston, Kalgan Chahar, China, College of Medical Evangelists, Los Angeles, 1930, medical missionary, director of the North China Sanitarium, for the Seventh Day Adventist Mission, aged 28, died, May 26, of diphtheria.
- Charles B. Duerson of Mount Sterling, Ky. University of Louisville School of Medicine, 1891, past president of the Montgomery County Medical Society, aged 63, on the staff of the Mary Childs Hospital, where he died, June 12.
- David Luther Barnard, Salt Lake City Northwestern University Medical School, Chicago, 1907 member of the Utah State Medical Association aged 54, on the staff of St. Mark's Hospital, where he died, May 21, of heart disease.
- Walter Edward Beattie of Alexandria, Va. Georgetown University School of Medicine Washington, D. C. 1929, secretary of the Alexandria City Medical Society, aged 29, died, June 9, in the Alexandria Hospital, of septicemia.
- James Edward Pridgen, Thomaston, Texas University of Texas School of Medicine Galveston, 1896 member of the State Medical Association of Texas, aged 62, died, May 7, in Cuero, of myocarditis and pulmonary edema.
- Henry Woodbridge Thayer, Bloomfield, N. J. Rush Medical College, Chicago, 1886 veteran of the Spanish-American War, aged 74, died, March 28, in the U. S. Veterans' Hospital, New York, of carcinoma.
- William Albert Nason of Roaring Spring, Pa. Eclectic Medical Institute, Cincinnati, 1887, Rush Medical College Chicago, 1892, on the staff and formerly superintendent of the Nason Hospital, aged 71, died, April 29.
- Charles Lee Austin, Norman, Okla., University of Maryland School of Medicine, Baltimore, 1882 aged 73, died May 5 in a hospital at Oklahoma City, of myocarditis, following an operation for removal of the prostate.
- Albert John Toering, Brooklyn, Columbia University College of Physicians and Surgeons New York, 1900, member of the Medical Society of the State of New York, aged 54, died, May 13, of carcinomatosis.
- William Paul McDavid, Parchman, Miss. Memphis (Tenn.) Hospital Medical College, 1910, member of the Mississippi State Medical Association, aged 48, died, April 24, in St. Joseph's Hospital, Memphis.
- Henry Bayon of New Orleans, Tulane University of Louisiana Medical Department, New Orleans, 1888 professor emeritus of applied anatomy at his alma mater, aged 68, died, in April, of coronary thrombosis.
- Thomas Joseph Dailey of Plymouth, Pa., University of Pennsylvania School of Medicine, Philadelphia, 1909 for many years on the staff of the Mercy Hospital, Wilkes Barre, aged 50, died, May 7, of carcinoma.
- Isaac Posnansky, New Orleans, Tulane University of Louisiana Medical Department New Orleans, 1904 aged 55 died May 8, in the Charity Hospital, of chronic myocarditis nephritis and diabetes mellitus.
- Neil Lawrence O'Herrin, Oak Park Ill., College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1912, aged 58, died, June 10, of heart disease and diabetes mellitus.
- Charles Wilbur MacConnell, Keansburg N. J., Omaha Medical College, 1891, member of the Medical Society of New Jersey, aged 67, died April 23, of bronchopneumonia and arteriosclerotic heart disease.
- Joseph Vadasz of Cleveland, University of Budapest and Royal Hungarian University of Science Hungary, 1909 aged 49, died, April 14 of perirectal cellulitis, pyelonephritis and gangrenous appendicitis.
- Ross Merrill Gamble, Albert Lea, Minn. University of Minnesota Medical School, Minneapolis, 1922 member of the Minnesota State Medical Association, aged 37, died suddenly May 6 of heart disease.
- Addison S. Robertson, Flemingsburg Ky., Hospital College of Medicine, Louisville, 1890, member of the Kentucky State Medical Association aged 66, died, April 15 of angina pectoris.
- Daniel C. Mills, New Lebanon, Ohio Medical College of Ohio Cincinnati, 1893, member of the Ohio State Medical Association bank president, aged 67, died, April 17, of heart disease.
- Louis Edward Walsh, Clarkdale, Ariz., University of Michigan Medical School Ann Arbor 1916 aged 50, died, April 6, in the Santa Fe Hospital, Los Angeles, of heart disease.
- Charles Evans Morris, Hartford Conn. University of the City of New York Medical Department, 1891 aged 66 died May 20 of diabetes mellitus and carcinoma of the rectum.
- Andrew Arthur Dechman, Bridgetown, N. S. Canada Dalhousie University Faculty of Medicine, Halifax, 1894 formerly mayor of Bridgetown, aged 72, died, April 21.
- R. Henry Hawkins, Fallon, Nev. (licensed in Nevada in 1924) member of the Nevada State Medical Association aged 76 died, February 19 of diabetes mellitus.
- John Fletcher Taylor, Buda, Ill. Rush Medical College Chicago, 1895 served during the World War, aged 59, died, March 1, of pulmonary carcinoma.
- Joseph Aloysius Moore of Philadelphia Jefferson Medical College of Philadelphia, 1902, pathologist to St. Joseph's Hospital aged 53 died, May 24.
- John Joseph Travis, Northport, Wash. Vanderbilt University School of Medicine Nashville, Tenn., 1881, aged 74 died April 8, of angina pectoris.
- Benjamin Franklin Beardsley, Hartford, Conn., University of Buffalo School of Medicine, 1865, aged 93, died, June 2, of arteriosclerotic heart disease.
- Benjamin F. Lockwood of Brooktondale, N. Y., Hahnemann Medical College and Hospital, Chicago, 1885, aged 72 died May 15 of myocarditis.
- Harriet M. Turner, Rochester, N. Y. Woman's Medical College of Pennsylvania Philadelphia, 1886, aged 81, died February 17, of myocarditis.
- Charles Clifford True, Port Clinton, Ohio, Homeopathic Hospital College, Cleveland, 1884, aged 83, died, February 12, of coronary thrombosis.
- Karl John Fauth of Wellsburg, Iowa, State University of Iowa College of Medicine, Iowa City, 1925, aged 36, died, May 17, of pneumonia.
- William Elzie Tyson, Chula, Ga., Chattanooga (Tenn.) Medical College, 1904, aged 55, died suddenly, March 6, of cerebral hemorrhage.
- Martin McMahon, Palmyra, Ill., Missouri Medical College, St. Louis, 1885, aged 75, died, April 29, in Peoria, of chronic myocarditis.
- George Augustus Post, Chicago College of Physicians and Surgeons of Chicago, 1889, aged 74, died, April 1, of chronic myocarditis.
- George Frederick Swinnerton, Los Angeles Medical Department of Hamline University, Minneapolis, 1906, aged 65 died, May 2.
- Grover Cleveland Miller, Chipley, Fla., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1910, aged 47, died April 7.
- William Henry Mills, Boonville, Ind., Medical College of Ohio, Cincinnati, 1880, aged 82, died, April 17, in Grand Rapids, Mich.
- Joseph Eugene Brown of Cincinnati, Cincinnati College of Medicine and Surgery, 1892, aged 66, died June 5, of heart disease.
- Wyatt Sanford Beazley of Richmond, Va. Medical College of Virginia, Richmond, 1893, aged 65, died June 6, of heart disease.
- Peter John De Pree of Grand Rapids, Mich. Detroit College of Medicine, 1906, aged 59, died May 15, of cerebral hemorrhage.
- Franklin Pierce Tilford, Nebo, Ky., University of Tennessee Medical Department, Nashville, 1898 aged 81, died, in March.
- Seymour Traynor, Victoria, B. C., Canada, University of Toronto Faculty of Medicine, 1905, aged 54 died, March 2.
- Bruce Downing Parrish, Mattoon Ill. Louisville (Ky.) Medical College, 1889, aged 67 died April 5, of heart disease.
- John W. Keckler, Greenville Ohio (licensed in Ohio in 1896) aged 69 died May 9 of diabetes mellitus.
- Berry Daniel Marshburn, Wendell N. C. (licensed in North Carolina in 1885), aged 80, died March 30.

## Correspondence

### IDIOSYNCRASY TO SALYRGAN

To the Editor —Dr L. J. Wolf's communication in THE JOURNAL, April 7, page 1177, describing two cases of fatal idiosyncrasy to salyrgan, has prompted me to refer to a third case which I had the misfortune to be responsible for. Early last year I had to treat a boy about 10 years of age who had rheumatic mitral stenosis and regurgitation. Edema developed. It was spreading and would not yield to ordinary diuretics and digitalis. The urine contained only a trace of albumin and there were no casts in the deposit. I gave him 0.5 cc of salyrgan diluted with 10 cc of double distilled water intravenously. The father of the boy reported to me next day that within less than five minutes of my departure after giving the injection the boy complained of sudden pain in the chest and collapsed. The boy had had no salyrgan before.

Prior to this accident I had given several intravenous injections of undiluted salyrgan without mishap. After reading a report in the *Proceedings of the Royal Society of Medicine*, London, about the danger of undiluted salyrgan given intravenously, I had before this unfortunate incident begun to dilute salyrgan. Subsequently too I have given many intravenous injections of diluted salyrgan and have had no trouble.

S. K. SUNDARAM, M.D. (Madras),  
King George Hospital, Vizagapatam, India

### DINITROPHENOL AND EXTERNAL HEAT

To the Editor —In following the cases in which the use of dinitrophenol has been reported, in THE JOURNAL and elsewhere, it has seemed to us that not enough emphasis has been placed on the regulation of the dosage with relation to the external temperature. A dosage of 300 mg daily has been given as reasonable by Tainter and others, when the patient has become habituated to the drug by lesser doses, starting at about 100 mg daily. From observation, we have come to believe that when the external temperature is above 80° F this dosage is likely to cause discomfort to the patient, with excessive sweating and a possible rise in body temperature. We would suggest that, during the time such temperatures prevail, the dosage be cut to about 50 per cent of what the individual tolerates well in cooler weather.

O. M. COPE, M.D.,  
HELEN C. COOMBS, PH.D.,  
New York

Professor of Physiology and Physiological Chemistry and Assistant Professor of Physiology, Respectively New York Homeopathic Medical College and Flower Hospital

### TREATMENT OF FRACTURES OF THE JAWS

To the Editor —In THE JOURNAL, May 19, page 1655, appears an article by Dr. Frederick B. Moorehead of Chicago on "A Better Method of Treating Fractures of the Jaws." The title implies that the author has something new to offer. The principle of the use of elastic traction in reducing fractures of the mandible has been employed for many years. Sauer wrote about this in Germany in 1889 and many others have done so since then.

In our book on "Fractures of the Jaws" Dr. Robert H. Ivy and I devote several pages to the use of elastic traction and give at least six illustrations of its use in actual cases.

I must take exception to two statements made by Dr. Moorehead. Early in his article he says "in fractures of the jaws

with displacement, immediate complete reduction is rarely possible." That is perfectly true if one does not begin treatment until two or three weeks after the injury, but in our nationwide experience we have been able to reduce completely the great majority of our fractures of the mandible with no anesthesia within seventy-two hours after the accident. There are, of course, some cases wherein treatment must be delayed and some cases that are not seen until many days after the injury. In these, elastic traction is definitely indicated.

The author writes later on that "fractures involving the ramus or condyle usually require no treatment. Displacement is rare." It has been our experience that condylar fracture almost invariably cause a perfectly definite deformity, familiar to those who see many such cases, and that, with the possible exception of fractures about the symphysis with loss of substance, this group is treated in the most careless manner, resulting many times in permanent deformity.

LAWRENCE CURTIS, M.D., D.D.S., Philadelphia

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

### HAY FEVER AND ASTHMA

To the Editor —About a year ago a patient came to me who suffered perennially with spring hay fever and only on occasion did she have asthma with it. The offending pollens were those of various grasses that come out around the last of May. The time was limited so I gave her (beginning of course with very dilute solutions) increasing doses of the pollen extracts every three days. About May 30 I had some three or four doses yet to give and therefore the amount given at this time was not very large. The day following this injection she developed hives and her lips became edematous. Her face was puffed. There was a slight asthma. Calcium gluconate was given intravenously and epinephrine subcutaneously. At the end of a week there was almost complete relief. It is surprising that she states that her symptoms as far as her hay fever is concerned were hardly noticed during the case, although she thought her asthma was worse. Since that time, even in the fall she states that in damp weather her asthma returns and she has occasional hives. Would I dare again inoculate her? Please advise treatment. Kindly omit name.

M. D. Illinois

ANSWER —From a perusal of this history it is evident that the symptoms noted were due to the injection on May 30 of the extract of grass pollens. It is true that they were slower in appearing than is usual, but the urticaria and asthma are typical of the systemic reaction that all too frequently follows the injection of pollen (and other protein) antigens. As the grass hay fever season, at least in the north and northeastern part of the United States, starts about the last week of May, it would have been better to give the highest dose just before this time. It is a general principle which should be strictly adhered to: to reach the maximum dosage just before the hay fever season begins, and then, if further treatment is given coseasonally, it is advisable to reduce the following dose to about one half or two thirds of this maximum dose and repeat this reduced amount during the pollinating season.

Most allergists give both preseasonal and coseasonal injections and many are also giving injections all the year round (perennial treatment of hay fever).

Systemic reactions will occur in spite of the greatest care but their incidence can be greatly diminished by individualizing the dosages for each patient. The best rule is to begin with a small amount and increase from 30 to 50 per cent with each injection, provided there are no reactions. However, if the site of injection shows a moderate local reaction it is better to repeat the last dose and increase more cautiously when there is local soreness results. If there is a severe local reaction it is advisable to reduce the amount and then increase with great caution. A systemic reaction calls for an immediate injection of epinephrine hydrochloride (from 0.5 to 1 cc of a 1:1000 solution) followed in a few days by a lower dose of the pollen extract. No injections of pollen or other protein antigens should ever be given unless epinephrine is available for immediate use.

The value of the calcium gluconate used here is questionable. These symptoms will subside spontaneously and will be quickly helped in most cases by epinephrine.

It is well known that systemic reactions are often attended by an improvement in the symptoms of the patient this would be in accord with the lessening of the fever but would not explain the aggravation of the asthma. As to why the asthma returned even in the fall and as to why hives occurred should be answered by a thorough check up. The patient should be questioned closely as to any possible new contact e. g., a dog or cat new food new pillows or mattress or a change of cosmetics. In addition, complete skin tests should be carried out not only for pollens but also for epidermal foods and miscellaneous antigens such as orris root or cottonseed. It may be that she is susceptible to ragweed as well as to grass pollens. This would explain the fall symptoms. In any case injections again of grass pollen extract are strongly indicated and should be started at once, the precautions mentioned should be strictly observed. The fact that she had this systemic reaction shows extreme susceptibility and indicates the need of further treatment.

#### PREGNANCY AT FORTY

*To the Editor*—A woman patient came to my office the other day. She said she was 42 years old she looked 30 years. She asked me if it was safe and possible for her to have a baby if she became pregnant. She is vigorous physically in good condition and used to exercise and work. She wants to be married and she wants a baby. What advice and information should I give her? Please omit name. M D New York.

*ANSWER*—There is no valid reason why this woman should not marry and try to have a baby. It is true that the risks of motherhood are greater in elderly primiparas but with good care during pregnancy and proper management during labor no serious mishap should occur. Should any untoward symptoms arise such as toxemia near term or should the patient have a moderate degree of pelvic contraction or a breech presentation it would be advisable to perform an elective cesarean section. In other words in a woman of 42 or more the indications for abdominal delivery should be extended but it is not necessary to perform a cesarean section simply because the woman is of advanced age.

#### KOILONYCHIA OR LATERAL SEPARATION OF NAILS

*To the Editor*—I have a patient about whom I would like to have some information. She is a woman of 35 years and is in perfect health. She is well nourished and has never had any serious illness. Recently she had a test made for tuberculosis the reaction was positive and a roentgenogram of the chest showed some old healed scars of tuberculosis and no evidence of active tuberculosis. The information I seek is about her fingernails. One or two of these show an unhealthy condition. The color is good but the layers of the nail seem to separate laterally rather than split lengthwise. Can you give me any information about this condition? W L LAMBERT MD Asheville N C.

*ANSWER*—"Lateral separation" of the nails is assumed to mean splitting off in lamellae. This is a rare condition according to the literature though it may be commoner than thought because overlooked by physicians and not reported when seen. Only one report has been found in the literature that of Bering, whose patient was a single woman of 21 with chloranemia. Her nails (Bering, S F Zur Kasuistik der Nagelerkrankungen, *München med Wchenschr* 50 1777, 1903) were spoon shaped (koilonychia) and split in lines convex toward the root of the nail the lamellar portions coming off painlessly during her work. The nail condition improved on application of adhesive tape in the depressions though in the light of more recent reports the improvement might easily have been due to treatment of the anemia.

Koilonychia may be caused by local trauma as that of nail biters or of coal handlers who grasp the coal bags with the finger nails. It is often due to the irritation of cleaning solutions and in other cases to eczema of the nail folds. Freezing of the fingers has also been held responsible. General disease notably hyperthyroidism, rheumatism anemia and particularly achylic chloranemia, may cause spoon shaped nails. A large percentage of cases, Cipollaro says 35 per cent are hereditary. Spoon nails have also been reported in syphilitic and neurasthenic persons and in patients with acanthosis nigricans and lichen planus, but the etiologic connection is doubted. Of many the etiology cannot be discovered.

The case cited in the query if it is a case of koilonychia seems to belong in the latter group. Removal of the irritation and the treatment of eczema and anemia have restored the nails to the normal condition in many cases. Unless some such etiology can be discovered care to see that the patient has a well balanced diet, including all the vitamins and that she protects her nails from injury particularly by avoiding roughness during manicuring and applies some oily lotion or cream

to the nail folds after washing, may be of benefit. The adhesive tape treatment used by Bering might be tried. Tuberculosis may directly or indirectly cause many nail deformities. The same deformities may be due to many other causes.

#### SYPHILIS AND BLOOD TRANSFUSION

*To the Editor*—In case blood from a syphilitic patient is used in giving a blood transfusion, would the patient who receives the transfusion be likely to develop a chancre at the site of the transfusion? How would the blood Wassermann reaction be in the person who receives the transfusion? Would it become positive immediately? If not how soon after the transfusion would it become positive? How soon would the macular or maculopapular rash which usually requires about eight weeks to appear after the ordinary syphilitic infection appear after the transfusion? Has syphilis transmitted by blood transfusion been reported very often? Have any cases been reported in which a blood transfusion from a person actively syphilitic did not cause syphilis in the person who receives the transfusion? Please omit name.

M D Minnesota

*ANSWER*—In all probability, whether syphilis is transmitted from donor to recipient in the course of blood transfusion depends on the stage of syphilitic infection of the donor. There is great danger if the infection is recent, i. e., at any time from the actual date of infection, even before the appearance of a chancre, up to the time of spontaneous disappearance of untreated secondary lesions, and probably either continuously or at intervals for two to four years thereafter. There are numerous reported cases of syphilis transmitted by means of blood transfusion. Infection of the recipient may occur even if the donor's blood Wassermann reaction is negative if, for example the donor has seronegative primary syphilis at the time of the transfusion. The recipient would not be likely to develop a chancre at the site of the transfusion, and the reported incidences of so called transfusion syphilis have all been direct blood stream infections, the primary lesion being completely absent. The blood Wassermann reaction in a recipient would not become positive immediately but requires a period of from two to six weeks to attain positivity. The secondary rash usually appears from six to eight weeks after transfusion. So far as is known there are no reported instances of the recipient's having escaped infection provided the donor had an active early infection, in the sense and within the time limits outlined. If the donor has been infected for a number of years and whether or not he has active lesions at the time of transfusion the recipient may not be infected. W L McNamara (*Am J Syph* 9 470 [July] 1925) reports several instances in which emergency transfusions were performed with donors who were known to have late syphilis. The recipients were followed for some months after transfusion with clinical observation and repeated Wassermann tests, but no signs of infection developed.

#### KHAT HABIT AMONG ORIENTALS

*To the Editor*—I read in *Collier's Weekly* that at Yamen Arabia and in other towns the people buy a bunch of khat a native herb sometimes called the flower of paradise lie down on a rug and pillow in market places for the purpose and chew this khat which exhilarates them and that they do this daily before going to work. Would you inform me just what that herb is and under what name it is known in America?

F T YOUNG MD Covington La

*ANSWER*—Khat, *Catha edulis*, of the family Celastraceae, is a plant grown in Abyssinia, Arabia and Somaliland. The leaves are chewed or made into an infusion and drunk like tea by the natives of those districts. It is locally known as kat, khat chaat, kus es salahin, tchaad, tschut, tohat, tohai or gat.

The chewing of the leaves is said to produce a vague sense of stimulation, and the drinking of an infusion of powdered leaves is said to cause a feeling of fullness in the head. It has been suggested that the so called stimulating effect of small amounts can be felt only by those accustomed to the drug.

The limited experience in the United States with this substance does not justify an opinion as to its possessing habit-forming qualities. A perusal of the literature available however, reveals nothing which would suggest that the drug has narcotic characteristics.

No extensive pharmacologic investigations have been made respecting *Catha edulis*. As a matter of convenience, however, the following references have been reviewed.

- Mosso U *Riv clin* 30 65 1891
- Chevalier *Bull gen de therap* 1911 pp 161 and 572
- Stockman R *Pharm J* 1912 p 676
- Stockman R *J Pharmacol & Exper Therap* 4 251 1913

According to Stockman both the leaves and the wood of *Catha edulis* contain at least three alkaloids. These have been designated cathine cathine and cathidine. Cathidine is the

least important, because of its insolubility in water and the fact that it does not form soluble salts. The other two alkaloids are quite similar in action.

Cathine sulphate in large doses produces a marked depression accompanied by paralysis of the voluntary muscles. Smaller doses produce excitement and increase reflex excitability. The alkaloid cathine is less depressant than the alkaloid cathine.

The substance is not mentioned in any of the federal or state antinarcotic laws.

#### FAMILIAL ICTERUS GRAVIS

*To the Editor*—I have a patient who is five months pregnant and who gives a history of having had five children all severely jaundiced during the first week after birth. Three of these babies died during the first four or five days. The patient has two living children, both well in every way. Can you suggest a treatment that might help in this case?

C W LOCKHART M D Mellen Wis

*ANSWER*—This is an instance of habitual or familial icterus gravis, which is uncommon. Its etiology, according to such authorities as Pfannenstiel, Ylppo, Ibrahim and Reuss, is the same as that of icterus neonatorum simplex, except that the former is a malignant form. The exact cause is unknown. Occasionally intra-uterine toxic or infectious processes are concerned, but syphilis does not appear to be a causative factor. The disease affects full-term strong children more frequently than premature infants and the jaundice appears early, even a few hours after birth. The urine contains bilirubin, the stool is highly colored and the blood shows a pronounced anemia with strikingly rich, nucleated red blood cells. In some cases, hemorrhages are observed in the skin, mucous membranes, the bowel and the umbilicus. Frequently there are cerebral disturbances, motor stimulation, clonic or tonic convulsions, bulbar symptoms such as difficulty in swallowing or breathing and other symptoms. The prognosis is bad but some children recover. Unfortunately there is no specific treatment, but symptoms should be treated as they appear. Blood transfusions are helpful. No way has been found of treating an expectant mother during pregnancy to avoid this serious condition. Undoubtedly there is a hereditary predisposition in some cases. There is one case on record (Hilgenberg, F C *Monatschr f Geburtsh u Gynak* 70 261 [Sept] 1925) in which a woman gave birth to healthy children in her first marriage but in her second marriage she gave birth to six babies, all of whom developed icterus gravis and died as the result of it. If the child born of the present pregnancy has icterus gravis, it is best to instruct the patient in methods of contraception.

#### RELATION OF PREMATURITY IN CHILDBIRTH TO A FALL

*To the Editor*—A pregnant woman Oct 30 1933, fell into a hole and suffered a contusion of the leg. She later vomited and continued to do so for several days. November 13 jaundice developed which lasted until December 16 one week before she was delivered of a viable infant. In the child hemorrhagic disease of the newborn developed. This was successfully treated and the child is now growing normally. Three points in this interesting case come up for discussion: 1 Can jaundice be caused by trauma during pregnancy? 2 It does occur I believe without that factor entering in. 3 The child was about three weeks premature. Could one ascribe its prematurity to a fall sustained almost two months before? 4 Is there any possibility that the hemorrhagic diathesis might be accounted for by the trauma sustained by the mother. Please omit name.

M D, Connecticut

*ANSWER*—1 Since the only apparent injury sustained by the patient from the fall was a contusion of the leg, the jaundice most likely did not result from the fall. However, if the patient suffered an injury to the liver it is possible for icterus to have developed as the result of this.

2 The prematurity almost certainly was not due to the fall. The only possibility of a relationship between the accident and the early onset of labor is that during the fall there was some damage to the placental site. Usually, however in such a case there is noticeable escape of blood from the uterus.

3 The jaundice in the mother and the hemorrhagic diathesis in the infant most likely have a common etiology or a definite relationship with each other. However, if the fetus in utero suffered direct injury from the fall, there may be some connection between the accident and the hemorrhagic diathesis. But direct injury to the fetus in utero is extremely rare.

If in the process of the fall the patient's abdomen struck the sides of the hole forcibly, damage to the child and the patient may have resulted. If, however, the abdomen did not come in contact with the sides of the hole during the fall it is hardly likely that any of the harmful effects noted after the fall can be attributed to the accident.

#### PROTECTION AFFORDED BY ANTITYPHOID INOCULATION

*To the Editor*—I have understood that in the U S Army, inoculation with triple typhoid vaccine for two successive periods of two or three years is believed to confer permanent immunity. May I ask what is the basis of this belief and whether in your opinion one would be justified in following this procedure in private practice beginning in childhood? Also is it established that one proved case of typhoid protects one for a lifetime against further attacks?

H G BULL M D Ithaca N Y

*ANSWER*—The belief that one or more courses of injection of triple vaccine will protect against typhoid rests on experience. A single course of such injections proved effective beyond doubt in the Great War. One certainly would be justified in following this procedure in private practice when there is obvious danger of typhoid infection. It cannot be stated that the protection given by any form of vaccination against typhoid is absolute and permanent, because an overwhelming infection might break down whatever resistance is present. It is stated on good evidence that, when a protected person does come down with typhoid, the disease is likely to be mild. The safest course would be to repeat the vaccination every third year if there is constant danger of infection, and, if an epidemic develops, revaccination should be practiced even if the time elapsed since the previous vaccination is less than three years.

After recovery from an attack of typhoid, the immunity is generally regarded as permanent or nearly so. Some statistics on this point show that, in cases of typhoid, special inquiry may bring out the history of a previous attack in about 2 per cent of the cases. Here it must be remembered that the immunity is effective only against the particular kind of organism causing the primary disease, that is to say, an attack of typical typhoid may not protect against paratyphoid or vice versa.

#### HAZARDS OF CEMENT INDUSTRY

*To the Editor*—I am desirous of obtaining information as to whether there are any particular industrial hazards connected with the manufacture and handling in industry of cement plaster and gypsum other than silicosis, burns and allergic dermatitis. I am interested in this from the point of view of insurance. Please omit name.

M D, Louisiana

*ANSWER*—A publication emanating from the U S Public Health Service (The Health of Workers in Dusty Trades I Health of Workers in a Portland Cement Plant, Public Health Bulletin 176, 1928) ably presents the hazards growing out of exposure to cement. A few years ago the Retail Credit Company of Atlanta, Ga, published a small pamphlet discussing the hazards connected with gypsum. These two publications fully will supply information as to the hazard connected with these substances. Silicosis is not a highly probable result of exposure to the dust of the substances mentioned. The silica content of cement is low. The limestone used in the manufacture of cement is not likely to contain more than 4 per cent of free silica, but the shale in cement manufacture may contain as high as 40 per cent of free silica. Although silicosis is a possibility, the chest condition occasionally found among cement workers is more likely to be a noncharacteristic pneumoconiosis. The same is true of gypsum. "Plaster" is a loose term that may be applied to a variety of mortars and cements. Some plasters as used, may contain a high content of free silica. In addition to the industrial disorders mentioned in the query, a few other conditions may be specified as a possible occurrence in connection with the manufacture and application of cement, plaster and gypsum. Among others are temporary deafness connected with impacted cerumen, pneumoconiosis, furunculosis and an increased incidence of pneumonia and other respiratory diseases.

#### CHRONIC NEPHRITIS AS CAUSE OF FETAL DEATHS

*To the Editor*—I have a patient aged 21 who has had three pregnancies all resulting in stillbirths at eight months duration. At the last one which I attended the fetus was macerated and the placenta was small and somewhat irregular giving the appearance of numerous old infarcts. Examination reveals no abnormalities except a moderate laceration of the cervix. Wassermann tests of both her and her husband are negative. I would appreciate information as to possible causes of this condition and suggestions as to treatment. Kindly omit name.

M D New York

*ANSWER*—The description of this case is suggestive of chronic nephritis as the cause of the habitual fetal deaths at the eighth month. The patient's urine should be examined carefully not only for albumin and sugar but also microscopically for casts and blood cells. Even if the macroscopic and microscopic examinations fail to show any abnormalities, a number of tests of renal function should be performed. Not infrequently, even

When these tests indicate that there is nothing wrong with the kidney function, evidences of nephritis appear during pregnancy hence gestation is an excellent test of kidney function in women. Usually women who have kidney trouble in pregnancy show more and more damage to the kidneys in each successive pregnancy. The blood pressure is nearly always elevated in these cases.

If this patient has outspoken nephritis at the present time, she should not conceive again, at least not until she shows signs of considerable improvement. If, however, there is no evidence of kidney trouble and she becomes pregnant, the urine and blood pressure should be carefully controlled at frequent intervals. If no evidence of nephritis appears, it may be helpful to give potassium iodide and mercury preparations by mouth on empirical grounds. It is advisable to induce labor when the child is definitely viable.

#### VACCINE THERAPY IN UNDULANT FEVER

*To the Editor*—A boy aged 13 complained of headache and a tired feeling and showed slight loss of weight. The onset occurred about March 3, 1934. A diagnosis of undulant fever was confirmed by the agglutination test for *Alcaligenes abortus* in a positive titer of 1:320. Vaccine therapy with a National Drug Company product was started March 30, the initial dose of 4 minims (0.24 cc) being repeated every three days for three doses. Then 8 minims (0.5 cc) was given every three days for three doses and 15 minims (1 cc) every three days subcutaneously. Following the vaccine the temperature would rise to between 100 and 102 F the next day and fall to between 99 and 99.5 the next two days. Occasionally the temperature would reach normal for two days but when vaccine was given would rise again and remain elevated. It has reached normal only once for two successive days. Vaccine has been given regularly every three days 1 cc until May 8 when the temperature rose to 104.5 in two hours following injection of the vaccine with chill, vomiting and diarrhea and has remained around 100 and 101 the past two days. The patient has been at rest in bed. Kindly advise whether vaccine therapy should be continued until the temperature remains at a normal level. Kindly omit name and address.

M D Pennsylvania

*ANSWER*—A febrile reaction usually follows the injection of *Alcaligenes (Brucella) melitensis (abortus)* vaccine. This reaction is usually accompanied by an increase in the intensity of symptoms. When the dosage is increased to 0.5 or 1 cc a more marked general reaction frequently occurs. In most instances the injection of a like amount of vaccine three days later will not produce so marked a reaction. If a second marked general reaction should occur the dosage should be reduced to half of the amount that produced the reaction for at least two injections, after which the dosage may usually be increased without the development of severe reactions. Following the development of a marked general reaction, the fever usually declines over a period of several days. The response to vaccine therapy has been best in those patients who have experienced a rather severe systemic reaction following one of the vaccine injections. The average course of vaccine therapy requires approximately 10 cc of the vaccine.

#### AMEBIASIS

*To the Editor*—1. Are *Amoeba endolimax nana* and *Giardia intestinalis* or *lamblia* considered harmless protozoa or could infection with them be responsible for cases of mucous colitis? 2. What is the difference between *Giardia lamblia* and *Giardia intestinalis*? 3. Is *Amoeba coli* considered harmless or pathologic? Kindly omit name.

M D California

*ANSWER*—1. Almost all protozoologists and many clinicians believe that *Endolimax nana* and *Giardia lamblia* are not pathogenic. No critical studies of patients infested with them has furnished evidence to support the contention that the parasites are harmful. Nevertheless, several clinicians have attempted to correlate various signs and symptoms with their presence. There is practically no evidence that *Endolimax nana* is ever responsible for symptoms, and it is fair to say that until some one demonstrates pathologic lesions due to *Giardia lamblia* and a closer correlation is made between symptoms in general and the presence of the parasite, it should also be considered nonpathogenic. There is no evidence that either form is the cause of mucous colitis.

2. *Giardia lamblia* and *Giardia intestinalis* are synonymous.

3. There is no scientific evidence to support the contention that *Endamoeba coli* is a pathogenic form. It is widespread, and the common occurrence in perfectly healthy adults and the low correlation between its presence and definite symptoms that might be ascribed to it, together with a mass of experimental evidence, clearly indicates that the species is nonpathogenic.

The whole subject of amebiasis is most recently treated in Craig C. F. *Amebiasis and Amebic Dysentery*, Springfield, Ill. Charles C. Thomas 1934.

#### DIETS FOR THOSE ALLERGIC TO WHEAT

*To the Editor*—I am allergic or sensitive to wheat foods and to apples both of which cause prolonged headaches not always but often severe, and vague indescribable gastro-intestinal discomfort—especially wheat. For a number of years I have used rye, corn and rice combinations. I have found that different lots of rye vary in quality so that frequent experimentation is required to evolve attractive breads and pastries and the result is often not at all satisfactory. Can you advise me as to recipes procedures and a source of supply so that I and others so unfortunately handicapped may secure palatable and slightly wheat free breads? My father was such a sufferer until in advanced years. My trouble developed severity at about the age of 50 and now at 57 seems to show signs of less severity.

H S BUCKINGHAM M D, Berwick Pa

*ANSWER*—For a full discussion of recipes, procedures and sources of supply for those who cannot eat foods that contain wheat the following references should be consulted:

Rowe Albert H. Food Allergy Philadelphia Lea & Febiger, 1931.  
Balyeat R. M. Egg Wheat or Milk Free Diets with Recipes and Food Lists Philadelphia J. B. Lippincott Company.  
Pamphlet which will be mailed on request by Ralston Purina Company.

If the correspondent is certain that wheat causes symptoms, the question of desensitization against wheat by injections of increasing doses of wheat extract may well be considered. Results in such cases are usually excellent and most patients who could not eat wheat foods can do so with little or no discomfort after they have taken a course of such injections. It is much more difficult, however, to protect a baker who inhales wheat flour while working in the bakery.

#### ABSENCE OF UVULA AFTER TONSILLECTOMY

*To the Editor*—The question signed M D New York appearing May 26 page 1784 concerning the absence of the uvula following tonsillectomy in cases in which it had not been removed at operation was of interest to me as I have observed a similar disappearance in two cases. In both instances there had been slight injury to the posterior pillars causing irregular healing with stretching of the soft palate. As healing advanced the uvula could be observed disappearing within the substance of the soft palate until no evidence of the uvula remained in one case and but a slight projection in the other. As both the pharyngopalatinus and glossopalatinus muscles forming the pillars of the tonsils have partial origin from the soft palate any injury resulting in tension of these muscles may cause a stretching of the free border of the soft palate with shortening or disappearance of the uvula. Unless observed frequently following operation this gradual change in the uvula may not be noted and its absence not discovered until some later period.

A P TIBBETS, M D Washington D C

#### SIMULTANEOUS IMMUNIZATION

*To the Editor*—I am the only active practitioner in a county of some 5,000 people in Wyoming and incidentally the county health officer. It was necessary to inoculate for diphtheria and vaccinate for smallpox those children of school and preschool age who had not availed themselves of an opportunity for immunization against these diseases in previous county programs. It was at this time that your reply appeared as to whether or not more than one immunization could be done at one time. I was doing the two at the same time. In something like 250 cases in which both the vaccination and the inoculation were done there have been no untoward results in any way. One injection of the alum precipitated toxoid and the multiple intradermal prick scheme for the vaccination against smallpox constituted the routine.

WALTER E RECKLING M D Lusk Wyo

#### POLLENS IN NEW YORK AREA

*To the Editor*—In *Queries and Minor Notes* in THE JOURNAL June 2 you discuss Pollens in New York Area. Your correspondent would be interested to know that heavily wooded sections deep in the Adirondack Mountains especially those away from farm lands give relief from hay fever. It is also true that in both Algonquin and Timagami parks in Ontario relief may be obtained. Regarding New Hampshire many sections of the White Mountains other than Bethlehem are also fairly free from hay fever. The New Hampshire Development Commission at Concord will gladly send a list of hotels and resorts in the White Mountains. Information regarding Ontario may be obtained from the Department of Interior Ottawa Canada. The patient should chiefly avoid resorts near farms and clearings where many weeds are to be found.

M D New York.

#### DERMATITIS FROM 'ANGEL HAIR'

*To the Editor*—I have seen a case of dermatitis from the handling of 'angel hair'. I did not realize such reactions were so uncommon till I read the note by Dr. Taussig in THE JOURNAL (June 2 p. 1874). A girl aged 10 years had been engaged in decorating the Christmas tree with 'angel hair'. Ten days later her right hand became swollen, febrile and tender with vesicles on the dorsum and between the fingers which in the course of several days became blebs. The entire process subsided in about a week under ordinary medication and to date there has been no recurrence of similar symptoms.

PAUL V MCCARTHY M D Aberdeen S Dak.

## Book Notices

**Heredity and Environment Studies in the Genesis of Psychological Characteristics** By Gladys C Schwestinger Edited by Frederick Oster. Cloth Price \$4 Pp 484 with illustrations New York Macmillan Company 1033

The author states in the preface that "this volume was prepared as part of an attempt to appraise the present status of knowledge in the field of eugenic research." The result is a fairly complete analytic survey of the studies of personality, the influence of heredity and environment and the means whereby these factors may be evaluated. Almost a third of the book is devoted to a description of the origin and development of various tests of intelligence and personality in general use. These tests are being constantly modified to meet changing conditions in different environments. Granted, the author says, all the drawbacks of language, social position and predilections as to success, the psychologist still offers the scores of mental tests as the best single evidence obtainable on the intelligence of human beings. Of considerable interest and importance are the studies of F N Freeman of tests of intelligence and personality in various members of the family living together and separated, of siblings at home and in orphanages and in particular of fraternal and identical or enzygotic twins. This offers as fertile a field for the study of the respective influence of hereditary and environment as has so far been presented. Some of the results have been corroborated by recent studies of diabetes and peptic ulcer and of moral (in the broad sense) tendencies in identical twins. Prevailing notions of the effect of disease and undernutrition on intelligence advanced by overzealous public health officials will require revising. There is no question about the effect on the intelligence quotient of disease conditions affecting the brain but the author quotes sufficient opinions showing that the former have no effect on these tests. The last section reviews studies of the modern tendencies in psychology and constitution offered by Kretschmar, Spranger, Watson, Freud, Jung, Adler and many others. New light may be thrown on personality by work such as Healy is doing in child guidance and of students of behavior of infants. Here and there sober criticism is offered by the author. It is an excellent compendium and has a large bibliography.

**La sténose hypertrophique du pylore chez le nourrisson** Par J Poucel chirurgien des hôpitaux de Marseille. Paper Price 20 francs Pp 108 with 16 illustrations Paris Masson & Cie 1934

This pocket sized volume is one of the practical medicine series being published at present in France. It is a complete well planned and well written as well as not too lengthy or verbose monograph on congenital pyloric stenosis. Not only is this condition discussed in its entirety from the medical standpoint, but the surgical aspect is considered at length. The plan of the book is similar to others of the same character. In eight chapters it discusses after a historical introduction the etiology, pathology, symptoms, methods of diagnosis (clinical, laboratory and radiologic) course, complications and treatment of the condition. The work is based on the personal experiences of the author as well as on the recent literature. A working bibliography of which is provided. Particular emphasis is placed on roentgen diagnosis as well as on its use in placing the indication for treatment. If less than 50 per cent of the barium mixture given the infant passes out of the stomach in three and a half to four hours the condition is surgical. As a matter of fact the author favors surgical treatment for congenital pyloric stenosis. Early diagnosis, early operation is the slogan of the book.

**The Merck Manual of Therapeutics and Materia Medica. A Source of Ready Reference for the Physician.** Sixth edition. Cloth. Price \$2.15. Pp. 1319. Rahway, New Jersey: Merck & Company, Inc. 1934.

The fifth edition of this book appeared in 1923. The present edition has been expanded to include modern developments. New sections have been added on many subjects in which particularly therapy has advanced; moreover, therapeutics has been expanded to include also prophylaxis, general treatment and psychotherapy. As the volume is now made up its pages include more than 1,200 devoted to therapeutics and the remaining 170 to laboratory techniques, dosages, materia medica, and a considerable amount of miscellaneous tabular data and similar information. In the section devoted to therapeutics, disease and disease conditions are alphabetically arranged. Under each heading there is a definition, followed by discussions of etiology, diagnosis, symptoms and treatment. There are many useful tables of differential diagnosis.

In the compilation of the work most of the leading textbooks on medicine and also leading textbooks in each of the specialties have been consulted. Dr. Bernard Fritus, professor of therapeutics in the University of Illinois College of Medicine, is responsible for the outline of therapeutics. A book of this kind obviously suffers to some extent in comparison with other textbooks on therapeutics by its emphasis on the proprietary products of the manufacturer who puts the book out. Thus, the section devoted to materia medica is largely a list of U. S. P. and Merck preparations, products of other manufacturers are merely indicated without reference to the name of the manufacturer. This occurs, for example, in relationship to such products as carbarsone and dilaudid. Perhaps, however, a distinct advance is indicated in the fact that products of other manufacturers are mentioned at all. The book is limited largely, if not almost wholly, to materials included in New and Nonofficial Remedies, with occasional exceptions, as in the case of pyridium which was however, once in N. N. R.

With minor restrictions this manual may be approved as one of the most useful guides to therapy thus far available. For a doctor who simply must treat the patient in many instances if only to hold the patient, its usefulness is apparent. Not only is the philosophy of therapeutics covered, but there are also innumerable specimen prescriptions indicating specifically the manner in which drugs are to be prescribed. The section on diphtheria taken as an example, is a fine indication of the way in which medicaments may be helpful in keeping the patient comfortable as well as in its directions for use of the specific methods that are necessary in this disease. The book is printed on thin paper in easily readable type. Altogether, it supplies a vast amount of exceedingly useful and practical data at a low price. It is a *vaude mecum* that a physician will want to keep on his desk and to carry about with him in his handbag.

**Oxidation-Reduction Potentials in Bacteriology and Biochemistry.** By L. F. Hewitt, Ph.D., B.Sc., A.I.C., Biochemist at the Belmont Laboratories, Sutton, Surrey, London County Council. Second edition. Paper. Price 2s. Pp. 81 with 26 illustrations. London: P. S. King & Son Ltd. 1933.

This small book is divided into five chapters. In chapter I the author would define life as a continuous oxidation-reduction reaction. To study such systems and to express the results in quantitative terms is the object of the book. The problem is essentially concerned with the energy necessary for the growth and existence of organisms and the search for a quantitative method to study reversible oxidation-reduction systems. Electrode potential measurements have proved exact and useful. Preliminary to the actual measurements, oxidation and reduction are discussed in the narrow meaning of the term and also in the wider electrotonic concept of atomic constitution. In the latter oxidizing properties are due to a tendency to part with electrons, reducing properties to a tendency to take up electrons. Chapter II is concerned with the practical methods of measuring potential differences. The indicator methods and direct electrometric determination are considered. The reasons for each step with the advantages, disadvantages, limitations and difficulties are discussed. Chapter III deals with systems of special biologic interest in which sulphhydryl compounds and some naturally occurring pigments have been studied. The

potentials of tissues and cells have been examined and the application of potential differences in the study of cell physiology have been explored. Chapter IV is concerned with bacteriologic applications and contains one third of the subject material of the book. The behavior of the peroxide-forming bacteria is different from the catalase-containing organisms. Some of the peroxide-forming bacteria are, however, deficient in other enzymes than catalase. The reducing conditions in bacterial cultures are regarded as a necessary result of metabolic activities rather than being due to the explosive liberation of reducing substances from the cells. Chapter V, of about two pages, is given to a general conclusion in which the author is sane, conservative and optimistic. Encouraging progress has been made by the use of the oxidation-reduction potential methods, especially in the realm of bacteriology. The book is valuable for laboratory workers with some training in physical chemistry, though it may be read with profit by the average physician. It contains a large list of references by about 150 different authors and is a reliable and stimulating presentation.

**Certain Samaritans.** By Esther Pohl Lovejoy, M.D., General Director of the American Women's Hospitals Service. Second edition. Cloth. Price \$3.50. Pp. 344 with illustrations. New York: Macmillan Company. 1933.

Against a lurid background of postwar fighting in the Near East, Dr. Lovejoy has painted a vivid picture of a great piece of medical work and a great piece of women's work. The American Women's Hospitals were organized during the World War as the challenge of America's women physicians, who found themselves without a place in the war plans of the government. Arriving in France too late to see much action before the armistice, they nevertheless rendered some fine service in the war-torn areas of France but found their greatest field later in alleviating the suffering of the innocent bystanders in that great war game, the Christian populations of Turkey and to a lesser extent the Moslem population of Greece. The story is well told, and no opportunity is lost to hold up the utter inhumanity and the cynical cruelty of war. In the old hospital at Scutari where Florence Nightingale gave the first great impetus to modern nursing, the Women's Hospitals ministered to the refugees, while below on the shining Bosphorus, within sight and hearing of these pitiful human wrecks, great liners swung at anchor, the music of their dance orchestras mocking the suffering so near yet never touching them. Not only in the Near East but in Japan as well, the American Women's Hospitals have served, and now they are beginning to render service in remote areas of the United States, with especial reference to maternity and child welfare. The story is an eloquent record of a great piece of work efficiently and gallantly done. Not least among the constructive achievements is the training given to native personnel wherever they went. Intensely earnest as the book is, the laughs that often crowded close to the tragedies have not been missed. For Americans, far removed from danger or want perhaps the most pertinent lesson in the book is that medical services can be rendered adequately without elaborately expensive surroundings. The book will be a worthwhile addition to any library.

**L'année thérapeutique. Médications et procédés nouveaux.** Par le Dr. A. Ravina. Huitième année 1933. Paper. Price 18 francs. Pp. 192. Paris: Masson & Co. 1934.

This volume like its predecessors, is replete with interesting abstracts from the current literature, giving special prominence of course, to innovations reported in French medical periodicals. A few of the items of interest are the treatment of chronic alcoholism and delirium tremens by injections of emetine hydrochloride (0.02 Gm.), the analgesic value of intradermal injections of distilled water into tender areas, atropine in large doses (2 mg. and more) in the treatment of parkinsonism and the treatment of fistulas by sclerosing injections of quinine ethyl carbamate or sodium salicylate. It is stated that hemorrhages in the mouth can be promptly checked by application of meat from a bird such as a pigeon or a chicken slaughtered at the time of use. The antidotal value of sodium nitrite against potassium cyanide poisoning is discussed. Gelatinotherapy in the treatment of empyema, is the injection of 2 per cent of gelatin in physiologic solution or

sodium chloride to which 1 2,000 of an antiseptic such as acriflavine hydrochloride, is added. A resuscitation by intracardiac injection of 0.3 mg of atropine sulphate is reported. In vitiligo, ultraviolet irradiation is combined with rubbing a 10 per cent solution of oil of bergamot in alcohol into the white spots, the plaques turn a bright red, which color persists for some time. Intravenous injections of acriflavine hydrochloride as well as of methylthionine chloride are employed in connection with irradiation in the treatment of this condition. In the pernicious vomiting of infants, intramuscular injections of maternal blood have given good results. It may be of interest to note that 33 per cent alcohol has been injected intravenously in doses ranging from 6 to 45 cc, with alleged benefit to patients suffering from pneumonia, bronchopneumonia and pulmonary abscess. It is stated that sodium amytal lessens reactions following lumbar puncture. In leukemia and Hodgkin's diseases general teleroentgenotherapy is recommended. The mentioning of these few items, picked at random, may serve to suggest that American physicians who can read French would profit by the perusal of this therapeutic annual.

### Medicolegal

**Malpractice Volkmann's Contracture Attributed to Improper Bandaging**—The plaintiff, a 7 year old boy, sustained a supracondylar Y-shaped fracture of his right humerus. The defendant physician set the fracture and "used adhesive tape at the wrist and on the outside of the arm to hold it in position, no tape going clear around at either place, but just to give support for a piece of tape to go over the shoulder and hold the hand up to the chest." By observing the radial pulse in the injured arm, the physician found it was not as strong as that in the other arm, so he cut the tape and lowered the arm a little until the radial pulse in both arms was the same. The arm was then supported in a loose sling. The next day the patient was taken to a hospital and, with the aid of a fluoroscope, the fracture was reset. The arm was then taped up as before. After three days the swelling began to recede and a 99 per cent reduction of the fracture was obtained. Later a Volkmann's contracture developed and the plaintiff, by his father as next friend, brought suit against the defendant-physician. It was alleged that the defendant negligently bandaged the arm and elbow so tightly that it stopped all circulation in the arm, causing ischemic paralysis, followed by Volkmann's contracture. There was a judgment for the physician and the plaintiff appealed to the Supreme Court of Nebraska.

The burden of proof, said the Supreme Court, in a malpractice case is on the plaintiff to prove negligent treatment and that such negligence was the proximate cause of the injury complained of. When a case demands the employment of scientific technic of which a layman can have no knowledge, then such negligence must be proved by expert witnesses. The medical experts called by the plaintiff did not point out any particular wherein the technic used by the defendant-physician was wrong. One witness stated that while it was thought in the profession that tight bandaging might cause Volkmann's contracture, yet it sometimes occurred when there was no bandaging at all. Medical experts called by the defendant testified positively that the Volkmann's contracture was caused by the fracture itself and that the bandaging had nothing to do with it. In the trial court, medical books were used in the examination of experts, and quotations from them were embodied in the questions put to the experts. While medical books, said the court, are not admissible as independent evidence of the opinions expressed therein if an expert has based his opinion on a particular authority, then a paragraph from such authority can be read in evidence to contradict the witness.

The Supreme Court concluded that the trial court had committed no reversible error in the admission of evidence and that the verdict of the jury was fully warranted. It accordingly affirmed the judgment in favor of the defendant-physician.—*11 Inters - Rance (Neb) 251 N W 167*

**Medical Practice Acts Board's Denial of Reciprocity License Upheld**—Maximilian L. Herzig applied to the California board of medical examiners for a reciprocity license to practice medicine, based on a license issued to him after examination, by the board of medical examiners of Nevada. The application being denied, Herzig petitioned the superior court, Los Angeles County, for a writ of mandate to compel the board to issue the license. From a judgment denying the petition, he appealed to the district court of appeal, second district, division 1, California.

In his application for a reciprocity license, filed Oct 2, 1929, Herzig stated that he had spent six years in the study of medicine and surgery, to wit, from September 1909 to and including July 1913 at the National Medical University of Chicago, from October 1916 to Feb 3, 1919, at the St Louis College of Physicians and Surgeons, and from the fall of 1924 to the fall of 1925 at the Royal University of Naples, Italy, that he had received the degree of doctor of medicine from each school, that his application for a reciprocity license in California was based on a license to practice medicine in Nevada, dated Nov 10, 1925, issued after written examination, and that he was also licensed to practice medicine in the states of Washington and Texas.

The record in this case shows, said the district court of appeal, that on Feb 18, 1924, the California state board of medical examiners refused to recognize credentials of any nature from the National Medical University of Chicago and from the St Louis College of Physicians and Surgeons. Petitioner Herzig was, therefore, unable to comply with the provisions of the medical practice act of California, which require an applicant to file "a diploma or diplomas issued by some legally chartered school or schools approved by the board, the requirements of which school or schools shall have been at the time of granting such diploma or diplomas in no degree less than those required under this act." Under these circumstances, concluded the court, there was no abuse of discretion either on the part of the board of medical examiners in refusing to issue the certificate or on the part of the trial judge in refusing to grant the petition for writ of mandate. The judgment of the superior court was therefore affirmed.—*Herzig v Board of Medical Examiners of State of California (Calif), 26 P (2d) 513*

**Malpractice Liability for Physician's Neglect in Treating Compensation Case**—If a physician, who is employed by a subscriber to the workmen's compensation fund of West Virginia to render medical and surgical aid and treatment to its employees, is so unskilful and negligent in his treatment of an employee, injured in the course of employment, that the injury is thereby aggravated, such aggravation constitutes a part of the original injury for which the employer is liable under the workmen's compensation act. No independent action is maintainable against the physician. The services rendered by the physician were in furtherance of the employer's business, under express authority of employment, and the acts of the physician are the employer's acts.—*Hunkelman v Wheeling Steel Corporation (W Va), 171 S E 538*

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk ( \* ) are abstracted below.

**Incidental Hyperguanidinemia and Tetany**—Dodd and Minot studied eleven cases in which it seemed possible that the increased guanidine might be sufficient to decrease the effect of the normal amount of calcium and so cause manifestations of tetany. In these instances the concentration of calcium in the blood was normal or as high as was compatible with the observed protein content of the serum according to the chart of Peters and Eisserson. In the instances in which roentgenograms of the extremities were taken there was no evidence of rickets. There were no changes in the inorganic phosphate values or the base bicarbonate of the blood sufficient to account for the tetany. When electric reactions were obtained they were typical of tetany and strengthened the argument that this diagnosis was correct in spite of the absence of the usual chemical changes in the blood. This contention was supported by the relief of the hyperirritability by calcium medication. The only positive observation that offers an explanation of the tetany is the increase in guanidine in the blood which occurred in every instance. The authors state that the clearest example of tetany induced by guanidine in the absence of other symptoms is afforded by experiments reported by Bryan, Minot and Chastain and that in clinical instances of tetany, the cause for the increase in guanidine, is not always apparent. Sometimes there is undoubtedly increased autolysis of the tissues. Usually there is a more or less severe condition of dehydration.

**Atelectasis and Bronchiectasis in Children**—Anspach draws the following conclusions from a necropsy and from roentgen and clinical study of the atelectatic bronchiectatic process of the lower lobe in fifty cases, throughout life in some and from infancy to puberty in others. 1 The small well defined triangular shadow with associated displacement of surrounding structures toward it frequently noted at the base of the lung in roentgenograms of children represents a lower lobe in various degrees of collapse. 2 While anomalous lobes

are frequently seen at necropsy, persistent consolidation or collapse of a supernumerary lobe in the region of the cardio-hepatic angle is rare. The smallest shadows were found to represent a regular lower lobe. 3 Necropsies of infants in whom the triangular shadow was present during life did not show dilated bronchi, but in children who continued to live changes in the triangular shadow appeared later, and bronchiectasis developed. 4 If air entered the collapsed lobe early, the triangular shadow fluctuated in size and was larger and less dense in proportion to the amount of inflation. If postural drainage was instituted early, these fluctuating triangular densities, even though present for years, did not always bring about bronchial dilatations. The triangular shadow is not "pathognomonic of bronchiectasis." 5 If the triangular shadow fails to fluctuate, bronchial dilatations may develop within a few months, but frequently the process covers a period of years. 6 These triangular patterns, when outlined by opaque oils, are frequently seen in adults with bronchiectasis and appear to be acquired rather than congenital. 7 The prognosis can be more accurately determined by observing the behavior of these shadows at successive roentgen examinations. 8 Atelectasis precedes and plays a prominent and most constant part in the development of a common form of bronchiectasis of the lower lobe. 9 The most common form of bronchiectasis in children is an acquired process. 10 Early and frequent drainage of the bronchi is essential if the development of bronchiectasis is to be avoided.

### Serum Calcium and Phosphorus During Pregnancy—

In order to determine the extent of the changes occurring during the course of pregnancy, Mull and his associates made oral examinations at intervals of six weeks on 358 pregnant patients 215 of whom returned for the final postpartum check-up. Only fifty-four, or 15 per cent, of the prenatal cases showed any evidence of dental change during the period of observation. Of the 215 examined post partum only thirteen, or 6 per cent, showed evidence of change with a total of sixteen incidences. A study of the serum calcium and phosphorus was made during this same period on forty-nine of the fifty-four patients who showed some evidence of dental change. Only fourteen of the calcium determinations failed to fall within the range for that interval of pregnancy in which they were made. Seven of these fell above the range and seven below. The twenty phosphorus determinations that fell outside the range were also equally distributed, ten above and ten below. Vomiting has been considered a possible cause of tooth destruction. Of the fifty-four patients who showed active tooth decay, exactly half experienced vomiting in various degrees, while the others were free from it. On the other hand, 60 per cent of all the patients observed had vomiting, although only 15 per cent of the total showed active tooth decay. Vomiting cannot, therefore, be considered a primary cause of caries. The possibility of an acid mouth was also considered, but since there was no demonstrable increase in the titrable acidity of the mouth during pregnancy acidity was ruled out. The authors' conclusion is that there is no direct relation between the teeth and the serum calcium and inorganic phosphorus levels during pregnancy.

**Method for Measurement of Engaged Head—Hanson,** in determining the size of the engaged head limits the measurements to the vertex, since the shadow of the occipitofrontal diameter is subject to distortion due to the inclination of the head along the pelvic axis and to the variable anterior or posterior rotation of the occiput. The diameter of the vertex to be measured on the roentgen film is represented by the greatest transverse dimension nearest to the occiput or lower pole of the head. Owing to the inclined and oblique position of the engaged head this is neither the commonly known biparietal nor the suboccipitobregmatic diameter but an inter-

mediate diameter which passes diagonally from a point in the postero-inferior quadrant of one parietal bone to a diametrically opposite point in the anterosuperior quadrant of the other parietal bone. Both its anteroposterior and its lateral obliquity may vary considerably, depending on the degree of rotation, flexion or inclination of the head along the pelvic axis. The dimension of the shadow cast by the diameter under consideration must not be subject to change with ordinary variations in rotation, flexion or inclination of the head. The diameter must be at a measurable distance from the sensitive film, so that a correct reduction may be made for its magnification. This requirement can be satisfied, provided the diameter in question is at a measurable distance above a definite landmark, such as the ischial spines, and provided also this landmark is in turn at a measurable distance above the sensitive film.

**Use of Dilaudid-Scopolamine in Obstetrics—Ruch** used dilaudid in 101 cases, of which fifty-nine were primiparas and forty-two multiparas. Dilaudid was used in the  $\frac{1}{32}$  gram (0.002 Gm) ampule form combined with  $\frac{1}{170}$  grain (0.0005 Gm) ampule of scopolamine hydrobromide and administered subcutaneously. Narcosis was begun in primiparas when the cervix was dilated from 3.5 to 4 cm and in multiparas when the cervix was dilated 2.5 cm if the quality of the uterine contractions was good. Forty-five minutes after the original dilaudid-scopolamine injection,  $\frac{1}{32}$  grain of scopolamine was repeated, forty-five minutes later,  $\frac{1}{260}$  grain (0.00025 Gm) of scopolamine forty-five minutes later,  $\frac{1}{260}$  grain of scopolamine, and every hour or so thereafter as needed  $\frac{1}{260}$  grain of scopolamine. Practically 80 per cent of the patients felt the effect of the dilaudid-scopolamine after ten minutes. In only one patient was the effect delayed thirty minutes and in none as long as forty-five minutes. There was no appreciable diminution of the uterine contractions in any of the patients and several seemed to have a better quality of contractions after being relaxed by the drug. In comparing the synergistic action of dilaudid-scopolamine with that of morphine-scopolamine there was no appreciable difference. There were two cases of asphyxiated babies, one within one hour after dilaudid and scopolamine was given and another two hours and forty-five minutes after the administration of dilaudid-scopolamine. There were no cases of asphyxia in private patients. Dilaudid was given rectally by suppository, in doses of  $\frac{1}{32}$  grain (0.003 Gm) to relieve afterpain. The suppositories were used on a series of twenty multipara patients and gave relief within twenty to thirty minutes. In twelve cases one suppository was sufficient to relieve the patient the entire night seven patients received a second suppository after five or six hours, and one patient obtained no particular relief.

**Sterilization by Transplanting Uterine End of Tubes—Slemmons** method of sterilization consists of excision of the proximal end of both tubes and their implantation in the uterine muscle. The tube is grasped with forceps near the uterus and the translucent mesosalpinx is exposed in a favorable light to demonstrate clearly the position of the blood vessels. A small round needle carrying from 6 to 8 inches of chromic catgut is passed through the mesosalpinx within the uterotubal angle and as near both structures as vascularization permits. The tube is firmly tied leaving the ligature-ends approximately equal. Moderate traction is made on the ligature and the tube is severed by an incision tangential to the uterus. A suture already at hand should be placed promptly to compress the vessels and approximate the edges of the peritoneal surface of the uterus where the tube was severed. A stab 1 cm deep is made at a convenient point, generally on the anterior aspect of the uterus. Before the stab is made, a suitable spot is selected for it by trial of one location or another where the mobilized end of the tube will reach without undue traction. One of the ends of the catgut ligating the tube is threaded on a small, round needle, passed from the bottom of the stab and brought out on one side. Similarly, the other end of the ligature is passed through the opposite side of the stab from within outward. And finally while an assistant pushes the amputated end of the tube into position the suture is tied, approximating the edges of the wound and burying the ligated tissue securely in the wall of the uterus.

Response in Pernicious Anemia to Brewers' Yeast—

After the diagnosis of Addisonian pernicious anemia was established Russell placed four patients on the regular ward diet without liver for a control period varying from three to five days in order to establish the level of the reticulocytes prior to treatment with brewers yeast (extrinsic factor of Castle), beginning with 1 drachm (4 Gm) three times a day and increasing the dose in three days to 2 drachms (7.8 Gm) three times a day. During the time of the administration of the yeast the patients received the regular ward diet without liver. After the response obtained by feeding yeast began to recede (except in one case), 3 cc of parenteral liver extract was given for three successive days and the reticulocytes were observed daily in order to determine the type of hematologic response. Red corpuscle counts and hemoglobin estimations were made at intervals of from forty-eight to seventy-two hours during the course of the experiment. A slight but definite reticulocyte response occurred after brewers yeast was added to the diet. This increase in reticulocytes occurred in from five to seven days, and the intensity of the response varied between 32 and 6 per cent. Following the administration of parenteral liver extract a second response occurred which varied between 12 (in one case in which the red corpuscle level was 2.9 million) and 26 per cent. Prior to adding brewers yeast to the diet the reticulocytes in all four cases averaged 0.8 per cent and were never above 1.7 per cent. From these results the author believes that one of the following conclusions seems justified: 1 That the gastric secretions of the four patients contained some intrinsic factor, but insufficient to prevent symptoms of the disease. 2 That small amounts of the specific product of extrinsic and intrinsic factors were present and administered in the brewers yeast or were present in the patients (possibly stored in the body owing to previous treatment) in amounts insufficient to prevent symptoms and were activated by the large amounts of yeast that the patients received. 3 That Castle's explanation is not correct and that small amounts of extrinsic factor (brewers yeast) alone are capable of stimulating hematopoiesis.

Trauma in Relation to Gastric Ulcer—Gray reports five cases in which trauma played an important part in the production or aggravation of preexisting ulcer disease. Three cases were diagnosed as acute traumatic peptic ulcer on the basis of epigastric injury and of the presence of blood in the vomitus or stool or both with roentgen observations strongly suggestive of the presence of ulcer. All three made a complete recovery. One patient who came under observation four months after injury presented a definite duodenal ulcer. Roentgen examination done six weeks after injury revealed the presence of a duodenal ulcer. During an observation period of eighteen months there was a continuance of subjective complaints typical of duodenal ulcer associated with constant epigastric tenderness. Repeated roentgen study showed a characteristic deformity of the duodenal bulb but at no time was there any evidence of stenosis. In the other patient severe epigastric injury aggravated a preexisting duodenal ulcer which had been dormant for seventeen years. In this patient some of

the symptoms may have been due to disturbance in function of an existing gastroenterostomy. The predominant disturbances, however, were associated with duodenal ulcer activity. The author concludes that acute traumatic peptic ulcer may follow the application of a strong blunt force to the epigastrium. The tendency in these cases is toward complete healing. External trauma as a factor in the pathogenesis of chronic peptic ulcer is still a debatable question. If the absence of gastric symptoms prior to the trauma is assumed to indicate a normal gastroduodenal tract, then it may be stated that chronic peptic ulcer may be caused by external injury. In view of accumulated experience however, the absence of gastric symptoms does not necessarily mean absence of gastric disease. Gastroduodenal ulcer may exist for years and produce no symptoms. It seems reasonable and logical to state that trauma does not produce chronic peptic ulcer but rather reveals preexisting ulcer disease. Preexisting ulcer disease may be aggravated by external trauma. The resulting disability depends on the severity of the trauma and the pathologic changes initiated by the accident. In order to prove that trauma can produce a chronic peptic ulcer there must be roentgen evidence of a normal gastroduodenal tract within a comparatively short time prior to the accident. Otherwise, the assumption that a chronic peptic ulcer was produced by trauma is entirely speculative.

Function of the Utriculo-Endolymphatic Valve—Bast presents two cases which show that the auditory division (cochlear duct and sacculi) of the endolymphatic system may be disturbed to the extent of collapse without damage or collapse of the vestibular division (utricle and semicircular canals). These cases further indicate that the 'utriculo-endolymphatic valve' is responsible for the maintenance of apparently normal pressure in the utricle and semicircular canals when the pressure in the sacculi and cochlear duct is suddenly reduced.

Argyria Nasalis—Monson cites a case of localized argyria of the nasal mucous membranes in a man aged 40, who was referred for a routine nasal examination, following an examination in the department for ocular diseases. He had had a nasal operation in 1923 and was instructed to use drops of a 1 per cent solution of strong silver protein twice a day. He continued the nasal drops as prescribed without interruption until 1932 when another physician advised him to discontinue them. He had no nasal examination or treatment after that. Examination showed a bluish green and slate gray pigmentation of the nasal interior, involving all of the nasal mucosa from the mucocutaneous junction back to, and slightly beyond the choanal rim posteriorly. Both middle turbinates had been removed, and two moderate-sized bluish gray polyps were visible in the upper and posterior part of the left nostril. The mucous membranes were hypertrophic and there was considerable mucous discharge. A postnasal examination revealed that the polyps in the left nostril were growing from the region of the left sphenoid ethmoid recess. The roentgen examination showed grayness of the right ethmoid cells. Because of the ocular symptoms, a diseased right ethmoid sinus and evidence of disease in the left ethmoid sinus a double intranasal ethmoidectomy was performed. Recovery was unevent-

ful The diagnosis was a subacute inflammatory reaction with marked edema of the mucous membrane of the nostrils, pigmentation of the superficial subepithelial tissues according to the clinical history, argyria

**Amyloidosis of the Bone Marrow**—To the three described forms of amyloid deposits in the bone or bone marrow—isolated instances of vascular infiltration in generalized amyloidosis, primary amyloid tumors of the bone and secondary amyloid deposits within blastomas or other diseases of the bone—Gerber adds a fourth type, that of diffuse amyloidosis of the bone marrow associated with generalized amyloidosis. The diagnosis made during the life of the patient was amyloid nephrosis, hypercholesteremia, hepatomegaly and lipid histiocytosis. The subsequent postmortem observations of generalized amyloidosis, with marked involvement of the kidneys and liver, serve to explain the hypercholesteremia and hepatomegaly. Despite a careful search at necropsy no explanation could be offered for the cause of the amyloidosis. The amyloid deposits in the internal organs, aside from those in the pancreas and kidneys, showed nothing of unusual significance. There was infiltration of the pancreas. The microscopic appearance conformed to that seen in similar reported cases. The clinical course of the patient presented a complete picture of amyloid disease of the kidneys beginning with the nephrotic syndrome and terminating with renal insufficiency. The signs and symptoms of nephrosis persisted for a period of more than two years, during which time the renal function and the blood pressure were normal. The gradual onset of renal insufficiency and the sudden appearance of hypertension were ascribed to incipient contraction of the amyloid kidneys, this was confirmed by the anatomic observations. In the author's case, the amyloid deposits were seen not only in the vessels but also in the reticulum and in the walls of the sinusoids. He believes that the diffuse distribution of the amyloid in the marrow in his case readily distinguishes it from the other forms of amyloidosis of the bone marrow. Contrary to the observations in amyloid tumors of the bone, no inflammatory reaction was present despite the extensive destruction of the bones and the marked atrophy of the marrow. The involvement of the marrow was undoubtedly responsible for the secondary anemia observed in the later stages of the patient's illness. The collapse of the vertebrae is comparable to that described in the case of amyloid tumor of the bone of the third thoracic vertebra reported by Mandl in which pressure on the spinal cord had led to compression myelitis. It is not unlikely that in this patient the pressure of the collapsed vertebrae on the nerves as they emerged from the intervertebral foramina was responsible for the muscular pains in the lower part of the abdomen. A study of the case indicates that the amyloid deposits were not secondary to an underlying blastoma. It the mass of amyloid, the surviving marrow cells showed a normal ratio of myeloid and erythropoietic cells. The diffuse involvement of the marrow speaks against the presence of an underlying blastoma. The presence of normal hematopoietic tissue throughout the marrow militates against the concept of diffuse myeloma with secondary amyloid deposits.

**Histologic Diagnosis of the Age of Pregnancy**—Ryerson and Sanes examined seventy placental fragments and made differential counts of the number of nucleated and non-nucleated red cells in the chorionic capillaries at different periods of gestation. Each specimen was fixed for sixteen hours

in a 10 per cent solution of formaldehyde. After being dehydrated in alcohol and chloroform, the tissue was embedded in paraffin. Sections were cut 8 microns in thickness and stained with hematoxylin-eosin. With low power magnification, villi containing capillaries were located. Then from 100 to 200 red cells were counted while the specimens were immersed in oil. The proportion of nucleated and non nucleated cells was calculated in percentages. In several cases differentiation of megaloblasts from normoblasts was attempted. The age of pregnancy was deduced from the patient's history, conception being postulated as having occurred seven days following the last menstrual period. Replacement of nucleated by non nucleated forms took place rapidly and almost completely during the second and third months. Therefore, if all the chorionic corpuscles are nucleated, the pregnancy is probably not older than two months. If more than 1 per cent are nucleated, the age is less than three months. If fewer than 1 per cent of the red cells are immature, pregnancy has passed beyond three months.

**Effects of Diverting Gastric Contents to Lower Intestinal Levels**—McMaster performed end-to-side anastomoses between the open pyloric end of the stomach and the progressively lower levels of the intestine from the duodenum to the colon, inclusive, in thirty-five dogs. The intestinal mucosa was increasingly more sensitive to gastric content from the duodenum to the colon. No duodenal ulceration followed gastroduodenostomy. Jejunal ulceration was noted in five of eleven dogs (45 per cent). Ileal ulceration developed in eight of ten animals (80 per cent) after gastro ileostomy. Each of ten dogs had marked hemorrhagic colitis subsequent to gastrocolostomy, and usually this led to secondary anemia. The mucosa of the distal half of the colon was much more sensitive to the acid gastric content than was that of the proximal half. Following anastomosis of the stomach to the lower portion of the ileum or colon, the blood chlorides and the weight fell rapidly and often there was a marked bloody diarrhea. The acid gastric content appeared to be the most important factor in the production of ulceration of the intestinal mucosa near the outlet of the stomach. As a number of intestinal ulcers occurred directly opposite the anastomotic stoma, the element of mechanical trauma from expulsion of the contents of the stomach cannot be entirely ruled out. The loss in weight in the animals with the anastomosis in the lower portion of the ileum or colon was due largely to failure of digestion and of absorption of food. This failure of digestion and of absorption of food, with resultant loss in weight was due (1) to reduction in the intestinal surface by exclusion of the proximal small intestine in which digestion normally occurs and (2) to the rapid elimination of food occasioned by the increased irritability and peristalsis in the lower portion of the ileum and colon resulting from the acid gastric content.

**Histologic Studies of Transplants of Kidney**—Wu and Mann performed six autotransplantations and eighteen homotransplantations of the kidney on dogs, of which five autotransplants and thirteen homotransplants were suitable for study. Sixty biopsies were made. A total of 180 histologic sections were examined. All of the autogenous and six of the homogenous transplants functioned alike until the transplant was removed at operation, the animal died or thrombosis in one or both vessels or pyelonephritis occurred. One homotransplant excreted urine only part of the time, and six others failed to do so at any time during the period of observation. Thrombosis was not the cause of the failure to function, because in such cases exploratory operations revealed the vessels to be patent, and the biopsy wounds bled and healed as usual. The autogenous and the homogenous transplants did not show distinctive changes in structure. In one as in the other, the glomeruli appeared normal, the tubules contained a varying amount of albuminoid material, dilatation or degeneration, and the capsule of the kidney had undergone organization and fibrosis. Quantitatively, in the case of the nonfunctioning homotransplants the tubules seemed to contain a greater amount of albuminoid material than usual. Both varieties of transplants may show a few small collections of mononuclear cells on the first one or two days following transplantation. In the homotransplant, however, the infiltration is soon present in excess of the amount of degeneration and is followed by necrosis and destruction of the parenchyma. On the other hand, in the autotransplant, the number of those cells appears to be somewhat proportional to the severity and extent of the degenerative changes, and it tends either to remain the same or to diminish. Although the course of changes that accrued from day to day was progressive in both cases, it seemed that in the autotransplant it was reparative, whereas in the homotransplant it was degenerative. No evidence was found to suggest the type of biologic factors which elicit the reaction between the host and the transplant after homotransplantation.

**Magnesium Sulphate in Hypertension**—Lissner presents clinical studies from which he concludes that intravenous injection of magnesium sulphate exerts a palliative effect on the reduction of hypertension and its secondary symptoms. It reduces intra-ocular tension. It exerts a marked influence on the course of the eye changes and aids absorption of exudate of retinal hemorrhages, with the hope of prevention of threatened blindness. There are no untoward symptoms from frequent injections of controlled amounts of magnesium sulphate intravenously.

**Response of Plasma Cholesterol to Injection of Insulin and of Epinephrine**—Bruger and Mosenthal state that the plasma cholesterol may occasionally rise or fall but usually remains unchanged following the administration of a single dose of insulin to diabetic and nondiabetic subjects. A rapid diminution of the blood sugar from a distinctly hyperglycemic level to one of hypoglycemia is, as a rule, associated with no significant change of the plasma cholesterol, the ingestion of orange juice or dextrose during profound hypoglycemia usually results in a marked fall of the plasma cholesterol. The administration of epinephrine in doses large enough to increase appreciably the sugar content of the blood is usually accompanied by no significant change in the plasma cholesterol. Insulin and epinephrine, separately, often produce a transient diminution in the corpuscle volume percentage, but the fluctuations in the percental corpuscle volume of the blood bear no uniform relation to the plasma cholesterol content.

**Failure to Produce Granulocytopenia with Bacterial Toxins**—Meyer and Thewlis performed twenty-six experiments similar to those of Dennis on nineteen rabbits in an attempt to confirm his results. Two of these were control experiments, as the rabbits received encapsulated sterile beef broth infusion rather than cultures of bacteria. The results do not confirm the conclusion of Dennis that encapsulated pyogenic bacteria, acting as a focus, produce granulopenia. Because of the authors' negative observations, they subjected the results of Dennis to close analysis. Examination of the results clearly shows a failure to produce distinct leukopenia of significant degree or duration except in two animals with *Bacillus pyocyaneus*. Though the total neutrophil count in the peripheral blood decreased in the two instances in which leukopenia occurred, there was failure to produce distinct relative granulopenia in a single instance. In one case a culture was made from outside of the capsule as soon as the abdomen was opened after death and this showed *B. pyocyaneus*, indicating that the capsule was not completely sealed. Subsequent injections of pure cultures of *B. pyocyaneus* in varying doses, directly into the peritoneal cavity, were not efficacious in producing leukopenia. Postmortem examination and careful examination of the capsule was done in every rabbit that died. In three instances the capsule was definitely not intact, in the others the capsule was intact and usually deeply embedded in thick white pus. Many of the neutrophils, in the two cases in which leukopenia and prompt death (within forty hours) resulted after *B. pyocyaneus* implantation, were large and degenerated at the time the leukocyte count was falling. These cells closely resembled the cells shown by Dennis. The bone marrow of these cases was however, normal in appearance or hyperplastic. There was no sign of degeneration of the cells as noted by Dennis. The experiments using *Staphylococcus aureus*, *Streptococcus hemoly-*

ticus and *Streptococcus viridans* usually resulted in leukocytosis and a higher level of neutrophil cells for several days with a gradual return to the preoperative level, or else a persistent, or sometimes progressive, leukocytosis. In a few experiments, slight temporary decrease in the number of leukocytes occurred, associated, except in two instances, with an increase in percentage of neutrophils.

**Cerebrospinal and Venous Pressures in Heart Failure**—According to Friedfeld and Fishberg, elevated venous pressure due to failure of the right heart is accompanied by increase in the tension of the cerebrospinal fluid. The cerebrospinal pressure is almost always if not always, higher than the venous pressure. When the venous pressure falls as a result of improvement of the heart, the cerebrospinal pressure also falls, although often there is a lag behind the drop in venous pressure. The cerebrospinal pressure is not elevated in left heart failure with normal venous pressure. The increased cerebrospinal pressure in right heart failure is due principally to engorgement of the intracranial and intraspinal vessels, but edematous swelling of the nervous tissues and meninges also participates. No evidence was obtained that the volume of cerebrospinal fluid is increased. Symptoms due to increased intracranial tension were not observed although the spinal fluid pressure rose as high as 45 cm of water.

**Spinal Anesthesia in Urology**—Foulds and Douglas found that the field of usefulness of spinal anesthesia has increased with their greater familiarity with the method. The contraindications have become fewer as they have gained experience. Since epinephrine has been used as a routine the number of cases with an alarming fall in blood pressure has been reduced to a minimum and the contraindications to spinal anesthesia in hypotension have been removed. By selecting cases suitable for each drug the results have improved. Though procaine hydrochloride in doses up to 150 mg is quite suitable for operations on the lower urinary tract untoward symptoms frequently followed the administration of larger doses for higher and longer anesthesia. Such anesthesia for renal surgery can be more perfectly obtained with fewer unpleasant symptoms by

the use of nupercaine in doses up to 20 cc of a 1,500 solution. The postanesthetic sequelae have been negligible and the postoperative complications fewer than with general anesthesia. The authors consider spinal anesthesia the anesthetic of choice in the majority of urologic operations.

**Improved Pyelo-Ureterography**—Howard emphasizes the fact that, in order to comply with the physical requirements of adequately filling the ureter and renal pelvis, escape of fluid at the ureteral opening must be prevented and physiologic intra-ureteral pressure obtained. The latter should not stretch but be sufficient to quiet peristalsis, about 20 mm of mercury. His method consists in the use of Garceau catheters of varying sizes to suit the opening of the ureter in hand, introduced from 4 to 10 cm through a large tube such as McCarthy's panendo-scope has. After sufficient time has elapsed to expel the air by the returning urine a buret containing the opaque medium is attached. The amount allowed to run in is determined by intra-ureteral pressure measured on a mercury manometer, which should reach about 20 mm. This amount of pressure apparently stops the secretion of urine for the time as well as the peristaltic waves. The method is not so successful when the ureter is very spastic, as in acute inflammatory states, or in the presence of a small stone as in acute renal colic.

**Diathermic Treatment of Retinal Detachments**—In the diathermic treatment of retinal detachment Schoenberg has the patient prepared as for any major operation on the eyeball. The eye is washed, the pupil is dilated and a fundus examination is made while the patient is on the operating table. Anesthesia is obtained by instillations of a 1 per cent solution of holocaine or butyn, a subconjunctival injection of a 2 per cent solution of procaine hydrochloride in the region to be operated on and, if the operative field is large an orbital injection of 1 cc of a 2 per cent solution of procaine hydrochloride is made. The conjunctiva is incised at a distance of about 10 to 12 mm behind and parallel with the limbus. The conjunctiva and tenon capsule are carefully undermined the episcleral tissue is

removed and the sclera is exposed and freed of any loose tissue that may cover it. Any bleeding is stopped by applying an epinephrine-cochine solution for a few minutes. If the bleeding originates from a larger blood vessel, the application of the tip of a hot probe will stop it. Glass retractors are introduced in such a way as to keep the tenon capsule away from the eyeball. A hook underneath one of the recti or a forceps holding fast the episcleral tissue near the limbus is used to pull the eyeball in the proper position so as to make the area to be operated on accessible. Needles designed by Sifur are driven in by the aid of the diathermic current. The intensity used is just enough to drive the electrodes through the sclera. The distance between the needle points is 2 mm. When the current reaches the choroid it produces a small area of coagulation. The distance between the applications should not be greater than 2 mm and the applications should surround the torn area. If the tear is at the ora serrata, the applications should be made in a semicircle surrounding the part of the tear facing the optic disk, the extremities of this barrage ending at the ora serrata. These applications are to be made on the scleral surface of the eyeball.

**Color of Skin Following Irradiation by Ultraviolet Rays**—Rogin and Sheard state that the use of the spectrophotometer affords an accurate method of recording the changes of color in the skin after ultraviolet irradiation. The initial erythema reaction of the skin following such irradiation is generally crisis-like but may also be plateau like or double crisis like. The course of the erythema is rhythmic or wave-like, persisting for weeks. In the same subject, the amount of pigment formed after ultraviolet irradiation is directly proportional to the degree of the preceding erythema. This statement cannot be made, in the light of the data at hand when comparing the erythema and the pigmentation following ultraviolet irradiation among different patients. The pigment follows a rhythmic course apparently independent of the course of the erythema. There are marked individual variations in the chronology of the waves which appear during the course of erythema and pigmentation. The fundamental hue or dominant wavelength of the skin following ultraviolet irradiation remains constant. The changes in the redness of the skin following ultraviolet irradiation are due to changes in the purity (saturation) of the hue.

**Roentgenologic Observations of Colon in Amebic Dysentery**—Ikeda observed that the roentgen appearance of the colon in amebic dysentery may vary considerably depending on the stage of infection, the extent and degree of involvement and the type of the lesion produced. On the whole, no appreciable changes are probably noted roentgenologically in the early stage of infection. Later fine, saw-tooth projections may develop along the wall, which probably represent small superficial ulcers and which may soon become obliterated by inflammatory edema and exudation. Fine feathery or thorny filling defects on the indurated wall probably signify a later stage of the same lesion in which the submucosa and muscularis are involved in an extensive inflammatory granulation

process. A somewhat characteristic deformity of the cecum and ascending colon is observed, roentgenologically, during the subacute or early chronic stage of the disease when there may be an apparent shortening or contraction of the wall, with induration and filling defects in varying degrees. These changes are rapidly eradicated by the institution of emetine treatment. An advanced amebic lesion, when diffuse and extensive, is not likely to be confused with cancer. When localized and obstructive, it may be mistaken for cancer, from which there is no roentgenologic means of differentiation. The roentgen appearance of the colon in amebic dysentery may be presumptive or suggestive of the disease but not positive or diagnostic without collaborating clinical and laboratory evidences. On the whole, it does not resemble the usual picture of nonspecific ulcerative or tuberculous colitis, nor does it simulate the typical appearance of a cancer of the colon. The roentgen examination of the colon is a positive means of determining the location, extent and degree of involvement in amebic dysentery and of observing the progress of the disease under specific treatment. A small area of fresh involvement or the reactivation of old lesions may thus be demonstrated, roentgenologically, during a period of continued clinical improvement and negative or inconstant routine laboratory evidence. Thus, the roentgen examination of the colon may prove superior and more accurate than other means of demonstrating the presence of active lesions in the treated or proved cases of intestinal amebiasis. The value of the roentgen examination of the colon in this disease, therefore, lies more in its use as a guide in the general management of the patient than as a means of positive diagnosis.

**Distribution of Liver Metastases from Primary Gastro-Intestinal Carcinomas**—Marting and Halpert state that of 127 primary carcinomas in the gastro-intestinal tract, metastases in the liver were encountered in forty-five. Twenty were primary in the stomach, four in the bile ducts, four in the gallbladder, seven in the pancreas, two in the cecum, three in the sigmoid colon and five in the rectum. Of the twenty gastric carcinomas four were located in the cardiac portion, seven in the body and nine in the pyloric portion of the stomach. Metastases in the liver from the carcinomas primary in the cardiac portion and the body of the stomach occurred in the right lobe predominantly in two, in the left lobe predominantly in three and in both lobes in six. From the carcinomas primary in the pyloric portion metastases occurred in the right lobe only in one and in both lobes in five. The exact location of the metastases in the liver was not recorded in two instances and metastasis occurred by direct extension in one. In the pancreatic carcinomas two were located in the tail, two in the head and three involved the entire organ. Metastases in the liver from the carcinomas of the head and the entire organ occurred in both lobes, from the tail predominantly in the right lobe. Of the four carcinomas primary in the gallbladder, metastases in the liver occurred predominantly in the right lobe in one and in both lobes in three. Of the carcinomas primary in the extrahepatic biliary ducts metastases occurred in the right lobe only in one and in both lobes in the other. In the two carcinomas primary in the intrahepatic biliary ducts, extension occurred throughout the liver. In the carcinomas primary in the cecum, metastases in the liver occurred in the right lobe in one and in both lobes in the other. Of the three carcinomas primary in the sigmoid colon metastases in the liver occurred in the left lobe in one and in both lobes in two. In the five rectal carcinomas metastases occurred in the left lobe in one, in the right lobe in one, and in the right lobe predominantly in one and in both lobes in two.

**Influence of Ischemia on Development of Tumors—**  
Orr produced fibrous scar tissue in the subcutaneous tissues of mice by the insertion of linen thread sutures, which were subsequently removed, after which healing was allowed to take place. Care was taken to avoid direct injury to the epithelium. Tar applications induced tumors more rapidly in these mice than in controls, and histologic examination showed that the percentage of carcinoma at the twenty-first week was twice that in the controls. Local injection of vasoconstrictor drugs produced an acceleration in tumor induction, more marked with epinephrine hydrochloride than with ephedrine sulphate. Carcinoma was increased with epinephrine, but not significantly with ephedrine, as compared with sodium chloride injected and noninjected controls, at the twenty-first week of tarring. Tumors appeared more rapidly than is usual when tar was applied after discontinuation of a series of ephedrine sulphate injections. The author discusses the results in relation to other work and certain concomitant conditions in cases of human cancer. He expresses the opinion that carcinogenic agents act on cells that have been deprived of a fully adequate vascular supply.

**Skin Reaction to Ultraviolet Radiation—**Peacock observed that the normal protection of the skin against the destructive action of ultraviolet rays is partly due to fluorescence of the horny layer, the retina is similarly protected by the fluorescence of the cornea and lens. The erythema reaction is an indirect effect of the action of the ultraviolet rays on the epidermis. Pigmentation is a natural sequel of prolonged erythema of the skin and is not a specific response to the rays. Pigmentation of the basal layer protects the dermis from the action of the rays. Skin that is pigmented following exposure to ultraviolet rays is also proliferating, with a consequent increase in the thickness of the horny layer, which affords

additional protection to the epidermis against further exposures to the rays. If it is desired to obtain the maximal absorption of the rays by the skin, it seems advisable to avoid marked reactions with consequent pigmentation and thickening of the horny layer. The increasing tolerance of patients to repeated doses of ultraviolet rays is apparent and not real, and is explicable as an increasing resistance to the penetration of the rays on the part of the skin.

Primary Carcinoma of the Liver Report of Case Successfully Treated by Partial Hepatectomy A L Ahel—p 684

**Malignant Adenoma of Prostate—**Dickson and Hill present a case of primary prostatic adenocarcinoma in a man of 30. Metastases were found in the pelvic, prevertebral, abdominal and thoracic and deep cervical lymph nodes and in the bone of the vertebral column. The latter involved especially the bodies of the seventh cervical and first dorsal vertebrae and adjacent portions of the spinal column and ribs, producing collapse of the vertebral bodies and a condition simulating Pott's "angular curvature," with compression and softening of the spinal cord, Froin's syndrome with xanthochromia and the sudden death of the patient. The changes in the spinal column were an indication of the tendency of a prostatic neoplasm to metastasize in bone, and were localized. The case differs from the unusual case described by Roberts, in which there was a continuous direct spread of the growth on the intraspinal surface of the dorsal wall of the spinal canal from the sacral to the cervical region, though his theory that there is an intra spinous pathway for the dissemination of prostatic carcinomas consisting of the spinal laminae with their ligaments and the lymph spaces connected with these structures might be considered in this case. In the present case the bony metastases were completely osteoclastic and showed no evidence of the osteoplastic process which is generally described as characteristic of prostatic skeletal metastases.

**Treatment of Gonorrhea with Gonococcal Vaccine of Low Toxicity—**Price and King prepare a vaccine of low toxicity for the acute stage of gonorrhea in the following manner. Gonococci grown on hydrocele agar (pH 7.5) in a triangular Roux bottle at 37.5 C for forty-eight hours, are washed off into a cylinder with 100 cc of physiologic solution of sodium chloride, this yields a suspension of about 180 millions of organisms per cubic centimeter. 1 cc. of tenth

normal sodium hydroxide is added and the cylinder is placed in the 37.5 C water-bath for two hours, after which most of the organisms are found to be in solution. The fluid is filtered through sterile lint, 1.5 cc of tenth normal hydrochloric acid is added and the cylinder is returned to the bath. After from fifteen to twenty minutes white floccules appear and these are centrifuged out of solution (3,000 revolutions per minute) and then suspended in 9 cc of sterile solution of sodium chloride. Tenth normal sodium hydroxide is added to the suspension drop by drop until a pH of 7.5 is reached when the precipitate appears to go into solution. To this 1 cc of formaldehyde sodium chloride (1 per cent) is added. This colloidal suspension of gonococcus protein constitutes the vaccine 1 cc of which contains the protein content of approximately 1,800 million gonococci. This preparation was employed in the treatment of forty-six men who were suffering from acute gonococcal urethritis. All injections were given (daily) subcutaneously over the gluteal muscles, the right and left sides being injected alternately. The initial dose in each case was 0.25 cc (450 million organisms), and this was increased to a maximal dose of 1.5 cc if no untoward manifestations occurred. Thirty-eight of the patients (82.6 per cent) showed a marked increase in the strength of their serum tests and a definite decrease in the severity of the clinical symptoms within ten days. In those patients who responded serologically to the vaccine a definite clinical improvement almost invariably followed within a short time, but the proportion of cases that subsequently presented symptoms of chronic infection was not lessened. Serologic results were disappointing in all but two cases. No acute complications occurred as a result of the vaccine, although it was administered during the acute stage of the disease. The number of acute complications—six (13.1 per cent)—occurring later in the course of the disease in patients treated by this method is definitely lower when compared with patients treated by ordinary routine methods alone (24 per cent). The type of gonococcal infection most likely to be benefited by treatment with this vaccine is that in which the patient is suffering from a chronic gonococcal complication, such as arthritis, and the blood, when tested by the complement fixation reaction reveals a low ( $\pm$ ) specific gonococcus antibody content. The author concludes that specific gonococcus antibodies tend to prevent the occurrence of severe acute complications and to shorten the acute stage of the disease but seem to have little effect in eradicating the infection from its localized sites in the genital system. This would account for the disappointing results from the use of gonococcus vaccines, prepared in all manner of ways, in the routine treatment of gonorrhea.

Studies in Dermal Leishmanoid—Brahmachari presents two cases of a rare form of dermal leishmanoid showing well marked hyperpigmentation in certain parts of the body with extensive areas of depigmentation in other parts. The pigment cells of the epidermis over the hyperpigmented areas contain much more pigment than the healthy portions of the skin.

There is a slight round-cell infiltration of the skin in the hyperpigmented areas. Both the patients (brothers) present more or less the same type of dermal lesions, e.g., (1) well marked areas of hyperpigmentation, (2) extensive areas of depigmentation, (3) presence of a small number of papules on the body, (4) localized erythema and (5) absence of nodule formation in the skin. A frequent feature in the blood of cases of dermal leishmanoid is the presence of eosinophilia.

\*Pulmonary Consolidations in Cases of Tuberculosis S S Jaikaran—p 350

**Pulmonary Consolidations in Cases of Tuberculosis**—Jaikaran believes that epituberculous infiltrations are truly tuberculous processes. Caseation and necrosis are the more destructive effects of tubercle bacilli and their products, while epituberculous infiltrations show the more successful reaction of the tissues. He describes six cases of extensive pulmonary consolidation in adults. Resolution, partial or complete, occurred in all. They bore a striking resemblance to cases of epituberculous foci. The peripheral consolidation in all active tuberculous foci is of the same nature as an epituberculous consolidation. He has made an attempt to demonstrate the unity of all tuberculous lesions. Destruction of tubercle bacilli and the destruction of fixation of tuberculin by the tissue have been regarded as two separate processes. The tuberculous lesion produced in secondary disease is determined by the degree to which one or both of the powers is developed. Pulmonary consolidations in tuberculosis may resolve at any stage of the disease, even after caseation and cavitation have occurred. When considerable fibrosis has taken place, however, complete absorption of all inflammatory products may be hindered.

**Toxicity of Scarlet Fever Toxoid**—Nagata used the method of Veldee for the testing of scarlet fever toxin and toxoid and observed that adult rabbits (more than 2 Kg in weight) usually react to from one half to one human skin test dose. The reaction of the rabbit ear test to scarlet fever toxin usually reaches its maximum in from twenty to twenty-four hours, though there are a few cases in which this maximum is reached in forty-eight hours. The susceptibility of the skin of the ear of the rabbit to scarlet fever toxin showed a local variation, the basal part and the thick part of the inner side being more sensitive than the point and the outer part of the ear. The skin reacts not only to essential scarlet fever toxin but also to a concentrated solution of bacterial protein. The degree of detoxification of scarlet fever toxoid can be determined easily. The toxicity of scarlet fever toxoid determined by trial with white pigs generally agrees with that determined by this method.

**Grape Sugar and Morphine Hyperglycemia**—Maeda demonstrated that the intravenous injection of hypertonic grape sugar in rabbits dissipated hyperglycemia in acute morphinism.

By studying the relation of morphine and grape sugar to glycogen of the liver, he has observed that 1 Morphine injection diminishes the glycogen of the liver 2 Intravenous injection of grape sugar causes an increase in the glycogen of the liver 3 The effect of morphine in diminishing the glycogen of the liver is destroyed by the intravenous administration of grape sugar 4 Intravenous injection of grape sugar has no effect on epinephrine secretion 5 Glycogen of the liver plays an important part in counteracting morphine

### Archives des Maladies du Cœur, Paris

\*Treatment of Endocarditis Lenta by Vaccinotherapy C Dimitracoff—p 246

**Precordial Leads in Electrocardiography**—Lian and his collaborators chose a series of points on the thorax for placing the electrodes in developing a new lead for electrocardiography. The technique was simple. They used electrodes of impolarizable metal made of a strip of tin either rectangular or circular and on which is attached a stem of the same metal to which the filaments of the electrocardiograph are attached. This electrode is surrounded by a band of flannel saturated with a solution of sodium chloride. The entire structure may be attached to the thorax with rubber bands. The leads found most satisfactory were with one electrode connected to the internal extremity of the third or fifth right intercostal space and the other to the manubrium of the sternum. This lead was then tried on hearts with sinus rhythm, auricular fibrillation and auricular flutter. Some errors of interpretation which are possible with the usual leads are no longer possible when this lead is used. This is especially true in bradycardia without visible adventitious P waves. With this new lead, however, auricular fibrillation may be easily seen if present. In certain cases of complete arrhythmia, in which it is difficult to differentiate with the ordinary leads between auricular flutter and fibrillation, this lead also serves to clarify the true condition.

**Vaccinotherapy of Endocarditis Lenta**—Dimitracoff reports the results of treatment of four patients with endocarditis lenta by autogenous vaccines. The technique of preparation of the vaccines is as follows. Once isolated, the streptococci are inoculated in 100 cc of broth prepared by adding 1 liter of water to 500 Gm of dried calf meat and allowing to stand from eighteen to twenty-four hours in the icebox. This is boiled and filtered through linen and Chardin filter paper. The volume is adjusted to 1 liter. Two parts per hundred of Witte's peptone, 0.5 parts per hundred of sodium chloride and 1/10,000 of dextrose are added and boiled for one minute. The pH is adjusted to 7.5. The bouillon is placed in separate containers and autoclaved at 120°C for ten minutes. *Streptococcus viridans* grows readily in this broth in twenty-four hours, but the maximum toxin production does not occur for forty-eight hours. After incubation for forty-eight hours at 37°C the inoculated bouillon is acidified by ten drops of glacial acetic acid to precipitate the toxin. Two hours later, 2 cc of solution of formaldehyde is added. The next day the culture is sterile. The flask is centrifuged at from three to four thousand revolutions a minute for at least ten minutes. The supernatant fluid may be poured off the adherent sediment. The sediment is emulsified with physiologic serum to obtain a concentration of 500 million organisms per cubic centimeter. The pH is adjusted to 7.8. Two parts per hundred of compound solution of cresol is added and the sterility verified. With the vaccine thus prepared three patients having endocarditis lenta due to *Streptococcus viridans* were successfully treated by intramuscular injection of the vaccine. In one patient aged 62, the recovery has continued for two years after the discontinuance of the vaccine treatment. In the second three years have passed since recovery. The third patient, a girl aged 14, was affected by an old rheumatic double mitral lesion and developed a febrile state following the grip. This lasted six months and the patient presented signs of cardiac insufficiency, fever and other clinical manifestations. The blood culture was twice positive for *Streptococcus viridans*. The autogenous vaccine

prepared and given for three months resulted in return of the temperature to normal and improvement of the endocarditis. Infectious process, which has endured for one and a half years. The fourth case reported was due to a hemolytic streptococcus and the patient died. In view of these experiences the author feels that in spite of many reported failures this method of treatment should be given further trial, especially in endocarditis lenta due to *Streptococcus viridans*.

- Campaign Against Cancer of Uterus H Guggisberg—p 481  
Multiple Sclerosis in Rumania A Kreindler—p 496  
Neuroses and Their Treatment in Light of Physiology S Fleischmann—p 487  
\*Histamine Iontophoresis A Kuppeli—p 489

**Histamine Iontophoresis**—Induced by favorable reports in the literature, Kuppeli resorted to histamine iontophoresis in various muscular and articular disorders as well as in localized circulatory disturbances. He applied the histamine in the form of an ointment or of a solution. For the practitioner he recommends the use of a histamine ointment consisting of one part each of histamine dichlorhydrate and distilled water and of sufficient glycerin ointment to make 100 parts. After the skin has been defatted the ointment is applied in a thin layer. A gauze compress saturated with the sodium chloride solution is placed over it and then the metal electrode is connected with the positive pole. The negative electrode is applied over a gauze compress that has been saturated with sodium chloride solution. For clinical use the author recommends a histamine solution applied by means of a gauze compress saturated with it. A current of from 5 to 10 milliamperes is sent through for about ten minutes, until an itchy feeling of warmth is felt at the anode. The skin becomes hyperemic and papules develop. The author asserts that the application by means of iontophoresis is much more effective than mereunction with histamine ointment. He employed histamine iontophoresis in approximately fifty patients and obtained favorable results in acute and chronic muscular rheumatism, in rheumatic peri-arthritis, in arthritis deformans, in refractory ulcers of the leg and in chronic edemas. The treatment failed in spondylarthritis, in periosteal neuralgias and in neuritides. Iontophoresis with histamine and potassium iodide counteracted the pain in a case of tuberculosis of the wrist and a stiffening of the elbow was likewise improved. The literature reports results also in Raynaud's gangrene and in thromboangitis obliterans. Histamine iontophoresis is contraindicated in patients with fever and caution is necessary in vasolabile neurasthenic patients and in allergic persons.

\*Late Hypotensive Action of Epinephrine Injected Intravenously L Herlitzka—p 698  
Local Heteroprotein Treatment of Arthritis U Rondelli—p 704

**Late Hypotensive Action of Epinephrine Used Intravenously**—Herlitzka administered 1 cc of a 1/100,000 solution of epinephrine to eleven normal persons and to twenty-seven patients having idiopathic hypotension, hypotension due to Addison's disease, essential hypertension, diabetes with hypertonia, hypertension secondary to renal lesions and arteriosclerotic hypertension. He found that in all cases the epinephrine had a rapid and constant primary hypertensive action which exhausted itself in from two to three minutes. This hypertensive action was followed by a more gradual and prolonged hypotensive stage lasting from twenty to fifty minutes. The hypotensive stage which may serve as a test of the vascular tonicity is greatest in hypertensive patients, slight in normal persons and nonexistent in persons having hypotension or an arterial system of slight tonicity. The secondary fall of arterial tension takes place at the systolic as well as at the diastolic pressure although it is less marked at the latter. The author did not find appreciable differences in the hypotensive curve of the various forms of hypertension. The intravenous injection of epinephrine does not seem to alter the frequency of the pulse, at least in the late period.

Reparation and Functional Repercussions on the Renal Ureteral Appa-  
ratus N Cirillo and I Bellori—p 248

**Hyperglycemia and Ketonuria Following Local Anesthesia**—Calzolari studied the glyceimic variations and the behavior of the ketonuria in thirty patients operated on under local anesthesia. In all the operations variations of the glyceimic rate were found in accordance with the type of operation. The behavior of the hyperglycemia was not identical in all cases. In some it became manifest a few hours after operation and in others it appeared late. In every case the resolution of the glyceimic curve was obtained by 1935 and never lasted more than four days. Clinically demonstrable symptoms were not always due to hyperglycemia. A marked increase in the glyceimic curve was often well tolerated without producing any disturbances. Simple administration of anesthetics such as procaine hydrochloride, scopolamine and morphine may produce a mild hyperglycemia, which terminates within twenty-four hours. In operations of short duration the hyperglycemia is erroneously considered to be the result of the anesthetic. The explicit action of the nervous system on the endocrine-sympathetic glycoregulation complex is an accepted theory. The oscillations appearing in the glyceimic curve are always limited and it is difficult to distinguish those caused by the local anesthetic. Of the cases examined 63 per cent showed ketonuria. The action of the anesthetic and of the nervous system is insufficient to explain the pathogenesis of the post-operative hyperglycemia observed in operations of a certain duration. The increase of reducing substances observed in patients finds its principal factor in the postoperative acidosis accompanied or not by ketosis. The author states in conclusion that postoperative hyperglycemia is only partially influenced by the anesthetic and by the action of the nervous system on the endocrine sympathetic glycoregulation complex. He attributes the hyperglycemia to physiochemical modification found in the blood of patients who have been operated on and determined by the extent of operative shock on the acid base equilibrium.

Gonococcal Intradermal and Serologic Reactions L de la Cuesta  
Almonacid—p 591

**Alkali Reserve in Lepers**—Herrera studied the alkali reserve in seventy-four lepers all adults of both sexes. The average figures of the actual acid base reaction are diminished in lepers. This confirms the advisability of administering an alkaline treatment to them. Acidosis is more intense in female lepers in patients under the age of 35 in patients suffering from nerve leprosy or having other forms complicated by nervous symptoms in patients presenting the leprosy reaction and in untreated cases. Acidosis becomes more intense in lepers who are placed under the influence of an albumin diet such as is generally the case in undernourished patients suffering from other diseases but not having leprosy when placed on the diet.

p 389  
Heredity in Tuberculosis V L Montero—p 402  
Folds in Roentgen Image of Diaphragm A Freudenthal Portas and  
P Barcelo—p 411

**Intradermal Reaction with Mycobacterium Leprae**—Montanes says that it is possible to obtain pure sediments of Mycobacterium leprae by homogenization of lepromas triturated

and treated with 10 per cent Koch's solution. By means of the intradermal reaction with emulsions of leprosy bacilli the author obtained 100 per cent of positive results in cured lepers and in patients with various diseases but without leprosy. In a group of 116 lepers the intradermal reaction, performed with the same emulsion, gave 14 per cent of positive results. The older the leprosy the greater the number of positive results. The percentage of positive results among lepers is greater in cases of the pure form of nervous leprosy, and also in cases of mixed forms in which the degree of nervous invasion is intense, than in other forms of leprosy. The intradermal reaction was followed by positive results in 80 per cent of the cases in which the disease was inactive and the presence of bacilli in the nasal mucus cannot be demonstrated. The author considers the positivity of the intradermal reaction of great value, especially in the diagnosis of cases in which the patients are going to be discharged as cured.

- Diabetes and Exercise J A Collazo and J Barbudo—p 453  
Role of Wolffian Body and Muller's Ducts in Formation of Uterus and  
Vagina Maria Luisa Quadras Bordes and B Pla Mayo—p 458

**Diabetes and Exercise**—Collazo and Barbudo state that the literature shows the clinical fact that muscular exercise (manual work, sports, gymnastics, massage and so on) produces the following effect in diabetes. The tolerance to carbohydrates increases in patients with the florid form, the acidotic complications grow worse in patients with grave forms of diabetes complicated by acidosis and the action of insulin is activated in cases of diabetes compensated by insulin therapy so that it is possible to reduce the dose of insulin. The authors determined the lactic acidemia and the glycemia before and after muscular exercise in twenty-one patients with diabetes (including patients with the forms of florid diabetes compensated diabetes and grave diabetes complicated by acidosis) and found that muscular exercise produces a slight increase (about 4 mg) of lactic acid of the blood in almost all patients, and a decrease of the glycemia in all of them. The authors interpreted the aforementioned results as meaning that exercise makes the muscles develop a greater capacity to assimilate and use dextrose from the circulating blood and makes the liver develop a greater avidity for the lactic acid of the blood which, once drawn to the liver, is used by it to form glycogen.

- \*Thick Abdomen Rost—p 361  
Traumatic and Nontraumatic Thickening of Dura with Microscopic  
Hematomas Simulating Brain Tumors A Jentzer—p 364  
Determination of Level of Blind End of Congenital Atresia of End of  
Intestine R Zenker—p 370  
Surgery of Nervous System Review G Jorns—p 372

**Thick Abdomen**—Rost states that there exist three types of thick abdomen: (1) that due to deposition of fat in the abdominal wall; (2) that due to deposition of fat within the abdominal cavity so-called intestinal fat; and (3) that in which without any actual increase in fat there is an enlargement of the circumference of the abdomen often associated with an increase in the size of the abdominal organs, notably of the intestine. Obesity in human beings is principally nutritional in character that due to endocrine disturbance being quite rare. Fat distribution is influenced by the glands of internal secretion and by the character of the tissue. This accounts for the difference in the male and female types of fat distribution and in eunuchoids. Obesity of thyrogenous origin is characterized by thick joints whereas in obesity of hypophyseal origin the joints may be slender but the face is fat. In obesity of nutritional origin the fat is deposited in the neck and the abdomen. The author performed feeding experiments on 165 rats in order to investigate the role of diet in distribution of fat. One group of animals was fed bacon in addition to the basic diet of noodles, gruel and milk; another group received lean meat in addition to the basic diet while a third group was allowed liberal amounts of the basic diet. To hasten fattening in several of the animals the author resorted to the method of P E Smith of puncturing the base of the brain through

the ear or through the occipital foramen. This method speeds up the fattening process to a remarkable degree. The feeding of young animals on a diet rich in meat, but restricted as to fat and carbohydrates, resulted in the enlargement of the abdomen without, however, an increase in the amount of fat either in the abdominal wall or in the intestine. The enlargement was due to an increase in the size of the stomach and of the intestine. Animals fed on a diet rich in fat and carbohydrates developed pronounced fat deposits in the abdominal wall and in the intestine. This, however, occurred only after the normal weight of the animal had been reached, that is, when the animal had arrived at the adult stage. The author's surgical experience in human beings coincided with his animal experiments. Young persons, as a rule, do not store up fat. In the obese young person the fat is deposited in the abdominal wall and not in the intestine. In the adult the tendency is first to store up fat within the abdominal cavity rather than in the abdominal wall.

 \*Investigations on Behavior of Reaction of Urine Following Resection of Stomach K Lion—p 671  
 Role of Anomalies of Position of Teeth in Pathogenesis of Sigmatisms D Weiss—p 673

**Etiology of Urticaria**—Uhlmann calls attention to the concurrence of urticaria with disorders of other organs, gastrointestinal disturbances, hepatic and renal diseases, menstrual disorders and infectious processes. Then there are certain foods and physical factors, particularly thermic influences, that may cause urticaria. A study according to uniform points of view is made difficult by this multiplicity of eliciting factors. Urticaria may be caused by exogenous and endogenous factors, but the point of attack in the skin is perhaps the same in both cases. Exogenous causes are, for instance, the galvanic current and toxic substances produced by certain plants or animals. The wheal formation is of especial significance in the study of the pathogenesis of urticaria. Microscopic examination reveals that, with rare exceptions, the wheals are located in the papillary layer and in the succeeding layers of the cutis. Signs of inflammation exist, the capillaries are dilated, there is serous exudation and frequently an emigration of leukocytes. In sections of wheals that exist for longer periods, it is often possible to demonstrate perivascular infiltrates, which evidently exerted pressure on the capillaries. The author calls attention to the theory that the capacity of tissues to absorb water is responsible for the development of the wheal. The experimental production of wheals is retarded or entirely inhibited if the blood supply is cut off. He shows that nerve conduction has no influence on wheal formation because wheals can be produced even if the sympathetic innervation is completely interrupted, and he concludes that wheal formation is due exclusively to local factors that exert a direct influence on the vascular wall. This fact explains the possibility of an urticarial eruption following external or internal application of the wheal producing substances. If these substances reach the surface of the skin, they penetrate to the superficial blood vessels and exert their action, if, however, the urticaria is due to endogenous factors, the wheal producing substance reaches the cutaneous vessels by way of the blood stream and attacks their walls directly from the lumen. In addition to this there is of course the possibility that under the influence of the substances the tissues of the skin liberate substances that are capable of producing inflammatory hyperemia and serous exudation. The hyperemic area which sometimes surrounds the wheal for a while, has an entirely different pathogenesis, for it is caused by a reflex mechanism. The author shows that fluctuations in the acid-base equilibrium may play a part in the development of urticaria.

**Reaction of Urine Following Resection of Stomach**—Lion discusses the reaction of the urine in connection with the problem of the formation of urinary calculi. Since phosphaturia is a preliminary stage in the formation of phosphate

calculi, he calls attention to the so called physiologic phosphaturia, also termed postdigestive alkalimuria. Bence Jones, who first observed this phenomenon, assumed that the acid required for digestion was withdrawn from the blood so that an excess of alkali was the result. This excess could be removed only through the kidneys and thus the urine became alkaline. Many investigators accepted this explanation, but others gave different ones. The author reasons that if postdigestive alkalimuria is caused by the excretion of the acid gastric juice, it must be concluded that in the absence of this acid excretion the alkalinity must likewise remain absent. Some observations seem to corroborate this, but others contradict it. The author examined the urines of thirty patients who had undergone gastric resection. In some the tests had been made also before the resection. The results of these studies are a complete corroboration of the assumption that digestive alkalimuria is connected with the hydrochloric acid secretion of the stomach. Whereas before the gastric resection a digestive alkalimuria was present, this was not the case after the resection, that is, after a hydrochloric acid elimination was no longer possible.

 \*Vitamin C and Propagation E Vogt—p 791  
 \*New Method of Application of Bee Venom in Rheumatic Disorders R Schwab—p 793  
 Organotherapy of Infectious Processes of Skin W Milbradt—p 794

**Children as Carriers of Typhoid Bacilli**—Laessing shows that typhoid cases among children amount to at least one third of the total number of cases. Even nurslings may contract typhoid or paratyphoid. Children remain, just like adults, carriers of the bacilli, but the chronic cases are less frequent than the temporary ones, and they are less often carriers of typhoid than of paratyphoid bacilli. After paratyphoid the proportion of temporary carriers amounts to 30 per cent of all cases. The predominance of the prolonged elimination of bacilli after paratyphoid may perhaps be the result of the technic of the examination. Children occasionally pass through abortive attacks of typhoid or paratyphoid, which are not diagnosed, and thus they may become the cause of many other typhoid or paratyphoid infections.

**Vitamin C and Propagation**—Vogt cites experiments on guinea-pigs, which prove that only 50 per cent of the animals receiving a diet deficient in vitamin C become pregnant. Moreover, the symptoms of scurvy resulting from a diet deficient in vitamin C are much more pronounced in pregnant animals than in nonpregnant ones, which proves that larger amounts of vitamin C are required for the intra-uterine development of the fetus. It was found that deficiency of vitamin C results in a high percentage (50) of abortions and that the extra-uterine development of the young animals is possible only if they are born with a certain supply of vitamin C. The author admits that guinea-pigs are especially susceptible to vitamin C deficiency and that consequently a certain reserve is necessary in comparing them with conditions in human subjects. Nevertheless these studies indicate that vitamin C should be given consideration in the etiology and therapy of various disorders concerning human propagation. He suggests that deficiency of vitamin C may eventually play a part in female sterility and also in some instances of habitual abortion or premature delivery. Moreover, the postnatal development is connected with the supply of vitamin C and there is some evidence that hydrops foetus universalis and icterus gravis neonatorum are caused by a deficiency of vitamin C in the diet of the mother. The author also touches on the relationship between vitamins and hormones. He points out that habitual abortion is often successfully counteracted by corpus luteum preparations and since a greater supply of vitamin C in the food seems to have the same effect, he assumes a biologic

relationship between them. This appears the more understandable since, besides the suprarenals, the corpus luteum is the only organ of the human organism that contains greater amounts of vitamin C.

**Bee Venom in Rheumatic Disorders**—Schwab found that the intracutaneous administration of bee venom was effective, but because of certain disadvantages of this method, such as headaches, vertigo and nausea, the resistance of the patients to the numerous injections was often difficult to overcome. For this reason he was gratified when Forster succeeded in preparing an ointment that contains the effective constituents of bee venom. Since application of the native venom to the intact skin was proved to be ineffective the ointment could be efficacious only if resorption could be insured. The resorption of the ointment, which has been proved experimentally and clinically, is facilitated by various factors. The ointment base is readily resorbable. The epidermis is softened by means of salicylic acid and the skin becomes scarified by the minute crystals contained in the ointment but this scarification is so fine that it is not visible. The author employed the bee venom ointment in more than forty cases of acute and chronic articular rheumatism, muscular rheumatism, sciatica and neuralgia. The preparation was always well tolerated. The ointment is applied daily for eight successive days with increasing doses. After this, the injections are suspended for about four days, and, if the result is not yet satisfactory, they may be repeated. In chronic articular rheumatism the treatment had to be continued longest. In discussing the mode of action of this bee venom preparation the author expresses the opinion that increasing immunization against the bee venom and against the rheumatism is the main factor. This is proved by the fact that the preparation was effective not only when applied to the diseased region but also when applied to indifferent portions of the body. It is probable that the action of the bee venom is promoted by the simultaneously existing hyperemia. The ointment differs from the bee venom preparations employed for injection in that it contains the native venom and thus comes closest to the original application in the form of the sting. Moreover the use of the ointment makes it possible to administer larger quantities without causing noticeable disturbances.

# Zentralblatt für Gynäkologie, Leipzig

\*Vaginal Ligation of Uterine Arteries in Gynecologic Hemorrhages M Henkel—p 1153

\*Histologic Changes in Anterior Lobe of Human Hypophysis Following Irradiation with Roentgen Rays E Stockl—p 1160  
Spontaneous Rupture of Uterus W Wlassow—p 1165  
Early Eclampsia H Offergeld—p 1174  
Mechanical Rupture of Papillary Psammocystoma in Girl Aged 22 G Sachs—p 1185

**Vaginal Ligation of Uterine Arteries**—Henkel emphasizes that the complete destruction of the genital function should be avoided in the treatment of uterine hemorrhages. He considers a radical intervention particularly inadvisable in women with myoma, for it is well known that in these patients the menopause as a rule develops much later than in other women, a fact which indicates a functional origin of the hemorrhages. It may be assumed that they have an increased secretory genital function, and its interruption on the basis of the average menopausal age would therefore mean a premature destruction of the genital function in these women. The author relates the clinical history of a woman, aged 34, who had had profuse and painful menstruation for about three years. Laparotomy revealed a submucous myoma involving the largest portion of the anterior wall of the uterus. An illustration of the operation shows that an oval section was removed from the anterior wall of the uterus. In the course of this intervention the uterine vessels had to be ligated. Since in numerous conservative operations for myoma the author had never experienced an impairment of the nutrition of the uterus following the unilateral ligation of the vessels, he decided to try to verify in this case whether the anastomoses with the ovarian artery would be sufficient to take care of the nutrition of the uterus. The result of this operation was that the woman had a regular, painless menstruation of two days duration. The author decided to resort to ligation of the uterine arteries

from the vagina in severe hemorrhages during the menopausal age, in the presence of small myomas and in their absence, and in cases of prolapse or retroflexion. He did it successfully in eight cases. The hemorrhages are thus reduced, but there is no sudden exclusion of the genital function. The technique of the vaginal ligation is comparatively simple. After the bladder has been pushed back, the two uterine arteries can readily be reached from the vagina and be ligated. A curettage of the uterus may be combined with this intervention. Examination of the material removed by curettage is helpful in excluding the presence of carcinoma. The author directs attention to experiences of Gottschalk and Küstner with the ligation of the uterine arteries. The latter recommended ligation of the uterine arteries not only on account of myoma but also in chronic metritis.

**Changes in Anterior Lobe of Hypophysis Following Irradiation**—The fact that roentgen irradiation of the anterior hypophysis is employed more and more in the treatment of menopausal disturbances and after surgical and roentgenologic castration induced Stockl to study the histologic changes produced by the roentgen rays. Studies on the hypophyses of rabbits convinced him that the anterior lobe of the hypophysis has a high resistance to roentgen rays and that, in view of the rather small doses that are generally employed in the irradiation of the hypophysis, it is not very probable that marked morphologic changes develop. However, it is impossible to draw conclusions as to conditions in human subjects merely from observations on animals, especially when the organ under consideration shows considerable differences in animals and man. The death of a patient thirty-eight days after roentgen irradiation of the hypophysis gave him the opportunity to study the changes produced by the treatment. The rays had been applied to two temporal fields, and 610 roentgens was the approximate total dosage. The author observed extensive necroses partly involving two thirds of the tissues of the anterior lobe. This proves that an irradiation with such a dose produces anatomic changes. The biologic changes produced with approximately the same dose have been described before. The author states that in Vienna it is customary to employ a dose that is about one half smaller, so that the total dose is only about two thirds of that applied in the reported case. Anatomic studies have not been made as yet in cases in which this dose was given, but the author assumes that even these doses cause histologically demonstrable, regressive changes.

\*Blood Pressure and Temporal Reflex S S Vermel—p 120

**Blood Pressure and Temporal Reflex**—Vermel examined the blood pressure in 100 persons suffering from headaches of neurasthenic type and exhibiting the temporal reflex previously described by him. The reflex consists of a prominent pulsation of the temporal artery on the involved side. The apparently hard vessel, tense pulse and loud heart tones suggested a state of arteriosclerosis. The investigation of the blood pressure, however, showed that instead of hypertension this condition was characterized by marked hypotension. In most of the cases the pressure was between 105 and 115, in many below 100 and in a few as low as 85. The author concludes that in the temporal reflex the artery is dilated, weakened and tortuous and that the dilatation is the result of an active process of vasodilators rather than of a paralysis of vasoconstrictors, because it is not preceded by an initial constriction. The temporal reflex is an expression of hyperirritability of the vasodilators. This hyperfunction of one part of the vasomotor system at the expense of the other, the vasoconstrictor, affects the blood supply of various organs and their functions. Patients who have the temporal reflex exhibit a general disturbance of the central nervous system, such as dermatographia, tremor, headaches, insomnia, irritability, poor memory and other manifestations diagnosed as neurasthenia.

**Nederlandsch Tijdschrift voor Geneeskunde, Haarlem**

78 1929 2052 (May 5) 1934

- Spectacles or Contact Glass H J M Weve—p 1930  
 \*Concerning Secrecy of Periodic Abstinence G van E Boas—p 1938  
 \*Heterophile Antibodies in Glandular Fever L Meijler and R J Siemcluk—p 1952  
 \*Infra Red Ray Treatment in Gynecology H Heymans van Amstel—p 1960  
 Primary Sarcoma of Portio Vaginalis in Uterus Bilocularis Case W J Oosterveld—p 1967  
 Incipient Pneumonia with Violent Pains in Region of Appendix J H Ziesel—p 1970  
 History of Diabetes J Koopman—p 1973

**Security of Periodic Abstinence**—Boas describes twelve cases of pregnancy following coitus on an exactly known day. He found that nine of these conformed to the recent point of view of periodic sterility, because conception occurred within the so-called vulnerable days. The remaining three cases seem to contradict this theory. One followed coitus on the last day of the postmenstrual sterile period and another on the eighth day before the expected menstruation, while in the last case three conceptions took place under extraordinary circumstances: the first and third pregnancy were conceived within and the second one without the fertile period calculated according to Ogino and Smulders.

**Infra-Red Ray Treatment in Gynecology**—Van Amstel states that infra-red rays have a stimulating influence on the growth and sex hormones. The author treated four menorrhagic patients aged from 16 to 19 with infra-red rays and obtained good results in all. Four patients aged approximately 30, presented menorrhagic and metrorrhagic changes after the treatment; the interval between menstruations of three patients was longer and the duration of the menstruation less, but the pain of menstruation had not subsided. The general condition of all patients showed marked improvement. The period of irradiation was from eight to thirty hours. The patients were always placed at a distance of from 40 to 50 cm from the lamp. Four patients presenting dysmenorrhea did not respond well to treatment. One patient, aged 33, had slight hypoplasia of the genitalia and severe menstrual pains of five years duration and showed complete disappearance of pain and a general improvement after twenty hours of irradiation. Three patients presenting amenorrhea menstruated regularly after treatment. The author treated successfully kraurosis of the vulva, vulvitis, colpitis, pruritus with eczema of the vulva and epithelial defects resulting from roentgen irradiation. He concludes that infra-red irradiation has a beneficial effect on abnormal uterine hemorrhages, especially in young women, and a stimulating effect on the general condition of the patient.

**Treatment of Adiposogenital Dystrophy**—Rachmann relates the history of a woman, aged 22 who has been under his observation for five years. She had the typical symptoms of adiposogenital dystrophy: infantilism, hypogenitalism, obesity, reduced basal metabolism, increased tolerance for carbohydrates and enlargement of the sella turcica. The tests of the function of the hypophysis indicated a hypofunction. Since it was evident that a pluriglandular disturbance existed the patient received periodically pluriglandular treatment. Hypophyseal, ovarian and thyroid preparations were given. The basal metabolism was constantly controlled in the course of this treatment. The amenorrhea disappeared. At first the men-

struation was irregular, but later it became regular and there was no further increase in weight. The patient also grew a few inches. The author emphasizes that the organotherapy can never be a complete substitute, and it should aim to stimulate the function of the hypophysis. He advises against roentgen irradiation of the hypophysis in patients with adiposogenital dystrophy. He admits that roentgen treatment of the hypophysis has produced favorable effects in acromegaly, but this condition is the result of tumor and hyperfunction of the hypophysis, and the roentgen treatment is effective in counteracting the symptoms of compression. In adiposogenital dystrophy he considers roentgen therapy permissible only in cases in which there are signs of cerebral compression.

**Diagnostic Value of Iodine Content of Blood and Urine and Basal Metabolic Rate**—Elmer and Scheps found that in cases of euthyroidism with normal or increased basal metabolism the iodine content of the blood and of the urine is normal. The conditions are similar in nontoxic goiter. In cases of hyperthyroidism not undergoing treatment the increased basal metabolic rates are accompanied by an increased iodine content of the blood, but increased elimination of iodine in the urine is noticeable only in the more severe cases. In hypothyroidism the reduction in the iodine content of the blood rarely of the urine, corresponds to the lowered rates of the basal metabolism. In atypical forms of hypothyroidism, the iodine content of the blood is either near the lower limits or the normal or slightly below normal although the basal metabolism is decreased. When present alone, neither the increased iodine content of the blood nor the heightened basal metabolism indicates a hyperfunction of the thyroid, only the simultaneous increase of the two values proves it indisputably. The normal iodine content of the blood (in cases not undergoing treatment) excludes hyperthyroidism. In the detection of hypothyroidism and of its atypical forms, the determination of the iodine content of the blood and of the basal metabolism is only of limited value, for the iodine content of the blood is only slightly decreased or normal and its variations may be explained by faulty technic and the decrease in the basal metabolism may result from causes other than the insufficiency of the thyroid gland. The normal iodine content of the blood in cases with a low basal metabolic rate does not exclude an insufficiency of thyroid.

 Quantitative Photometric Determination of Bilirubin Content of Serum K Brychner Mortensen—p 482

**Cholecystography**—Foged reports on 401 cases of cholecystography in 388 patients. Normal cholecystograms were seen in ninety-one of ninety-seven patients without symptoms from the hepatobiliary tract. In 214 cases of cholelithiasis and cholecystitis 191 showed pathologic cholecystograms. Cholecystography verified the diagnosis in 30 per cent of the case, and supported the diagnosis in 90 per cent. The cholecystogram gave diagnostic information in nine out of ten cases of pericholecystitis. In some cases of cancer of the gallbladder and the biliary ducts of hepatitis and of cancer of the liver and in patients under observation for cholelithiasis the result of cholecystography as a rule agreed with the clinical picture. A normal cholecystogram does not definitely exclude a pathologic condition in the biliary tract. In more than 90 per cent a pathologic cholecystogram means a disturbance of the liver or of the biliary tract. Sandstrom's oral fractionated administration of the contrast substance is recommended as the normal method. Suspected disorder of the biliary tract is an indication for cholecystography. There is no absolute contraindication. On the basis of comparison between cholecystography and direct roentgen examination in 158 patients, the latter is regarded as usually superfluous when cholecystography is done.

## CLINICAL TYPES OF THERAPEUTIC PNEUMOTHORAX AND THEIR SIGNIFICANCE

J W CUTLER, MD  
PHILADELPHIA

Of all forms of treatment in pulmonary tuberculosis, therapeutic or artificial pneumothorax occupies an increasingly important position and today it is practiced in approximately 50 per cent of all cases of tuberculosis. Rist considers it the most remarkable advance made thus far in the treatment of pulmonary tuberculosis. It has undoubtedly considerably improved the prognosis of certain very common forms of this disease that formerly were regarded as invariably hopeless.

From the clinical point of view, one may consider several types of artificial pneumothorax: total collapse (complete collapse, compression pneumothorax), incomplete collapse, selective collapse (hypotensive pneumothorax, partial pneumothorax, expansile pneumothorax), simultaneous bilateral pneumothorax, and alternating pneumothorax. It is my purpose in this paper to describe in brief these various forms and to emphasize the clinical significance of each as well as some of the more important indications.

### TOTAL COLLAPSE

When Carlo Forlanini first practiced pneumothorax in 1884, he assumed that for the pneumothorax to lead to cure it should be complete—that is, both the healthy and the diseased part should be collapsed—and that the intrapleural pressure should be such as to assure absolute and uninterrupted immobilization of the entire lung. Only in this way could there be any healing of the tuberculous process. Consequently when pneumothorax was indicated the lung was shrunk to a more or less elongated hemispherical or sausage-shaped mass (figs 1 and 2). Under such circumstances, treatment could be instituted only when the contralateral lung was free of disease. Dyspnea, general discomfort, pleural effusions and reactions and displacement of the mediastinum were frequent and troublesome complications, and pneumothorax gained little headway.

As time went on, clinical experience forced the conclusion that absolute immobilization of the entire lung was not essential to healing. It was observed time and again that, even with an imperfect or incomplete collapse, because of adhesions (fig 3) notable results were attained. Furthermore, the marked beneficial effects of the pneumothorax that were so frequently observed at the very beginning of treatment occurred at a time when total collapse had not yet been established.

Pondering over these clinical facts, Ascoli in 1912 made the next most important contribution to collapse therapy when he urged the abandonment of complete collapse in favor of partial collapse, or, as he termed it, hypotensive pneumothorax, that is, pneumothorax accompanied by low manometric readings or negative pressure. It was not long before this teaching took root and operators in different parts of the world soon applied this newer conception of pneumothorax therapy in their practice. With inevitable refinements and developments in technique the hypotensive pneumothorax of Ascoli became the selective collapse of today, a term first used by Barlow and Thompson in 1921.

### SELECTIVE PNEUMOTHORAX

The primary object of selective collapse as it is understood today is to maintain uniformly and continuously complete collapse of the diseased part of the treated lung and at the same time permit full function of the healthy part (figs 4, 5, 6 and 7).

The mechanics of selective collapse is relatively easy to understand. When air is introduced into the pleural space under negative pressure and the patient subsequently studied under the fluoroscope, it will be observed that the air has a tendency to localize itself around the diseased area of the lung regardless of whether the disease is located in an upper or a lower lobe. This is a natural phenomenon and takes place of its own accord, provided the factors necessary for its production are not too violently disturbed. The explanation for this phenomenon is usually given as follows:

The tuberculous tissue having lost its elasticity is less able to resist the pressure of the induced pneumothorax and with each breath expands less and less. On the other hand, the healthy part of the treated lung with its elasticity unimpaired can and does resist the pressure of the induced pneumothorax. With each inspiration it expands freely to the chest wall and recedes on expiration. On inspiration, in order to make room for itself, the healthy part drives the air in front of it and forces it into the path of least resistance, which is toward the diseased area. This expansive action of the healthy part by repeatedly compressing and forcing the imprisoned air in the pleural cavity toward the diseased area little by little completely collapses the diseased part and then keeps it collapsed indefinitely. Given enough time, the constant hammering of this expansive force will cause satisfactory collapse of a diseased area in spite of apparently obstructing adhesions, and unyielding cavities will slowly give way and become completely obliterated without subjecting the patient to the dangers and disadvantages of complete collapse of the entire lung.

The phenomenon of selective collapse is thus viewed as an automatic mechanism, the resultant action of the

simultaneous tendency of the diseased part to collapse and of the healthy part to expand

Selective collapse has greatly widened the indications for pneumothorax therapy and has made it possible for patients with extensive bilateral disease to participate in its benefits. It minimizes respiratory disturbance, prevents circulatory distress and throws the least amount of work on the contralateral lung. It has reduced the incidence and seriousness of pleural effusions and is undoubtedly the procedure of choice.

The technic necessary for its production and maintenance is much more exacting than for complete collapse and depends for its success on close attention to the refill interval, the quantity of air administered, manometric readings, and routine fluoroscopic studies before each refill. Even under skilful guidance the healthy part of the lung may become adherent to the chest wall and the pleural space subsequently lost.

#### SIMULTANEOUS BILATERAL PNEUMOTHORAX

With the principle of selective collapse established, the next logical development in pneumothorax therapy was simultaneous collapse of parts of the two lungs. Ascoli is credited as the first to practice simultaneous collapse. It is undoubtedly the most difficult type of pneumothorax therapy to carry on successfully and requires the closest attention to detail. It is applicable only in a limited number of cases, and when applied judiciously the results are satisfactory. The best type of case is one in which the lesions are not too far advanced and are definitely limited to the upper lobes or when there has been a recent spread of the disease in the contralateral lung,

The following is an interesting example

CASE 1—S. S., a man, aged 23, came under observation, Dec. 19, 1929, with acute pulmonary tuberculosis involving the right upper lobe and complicated by severe hemoptysis. Therapeutic pneumothorax was instituted, December 21, and the patient responded well. Bleeding ceased almost instantly and within a month the temperature was normal. His recovery continued uneventful and by September of the following year he resumed

Fig. 3—Incomplete collapse of left lung. In some cases an ideal collapse is not possible because of numerous adhesions, yet the collapse established is sufficient from the clinical standpoint to close cavities and permit healing. Such a pneumothorax should not be interfered with. The patient has had his collapse maintained for over six years during which time he has been self-supporting and leading a normal active life. The shaded area in the diagram represents collapsed lung.

Fig. 4—Advanced tuberculosis of the right upper lobe.

full duties as a practicing attorney. Everything continued well with the patient self-supporting until January 1933, practically three years after his first breakdown, when a bad cold developed, with resultant spread of the

tuberculosis in the "good" or left lung and the sudden appearance of two small cavities in the mid-lung field. Because of the unusually good result obtained with pneumothorax on the right side and the prospect of a complete anatomic cure and the natural apprehension of the patient, it was not deemed desirable to discontinue the first pneumothorax. Accordingly a second pneumothorax was established on the left side, Jan. 23, 1933.

Within two weeks the patient was back on his job with no symptoms of tuberculosis and no discomfort from the double-sided pneumothorax. Fifteen months has now gone by and the disease in the left lung is undergoing slow absorption. The collapse is continued on both sides and the patient is happy and hopeful. No other form of therapy could have solved the patient's problem so effectively and so pleasantly. The only inconvenience is the frequency of refill. Figure 8 depicts the state of collapse of the lungs shortly after the bilateral pneumothorax was established.

The chief disadvantages of simultaneous collapse are the difficulty of management and the frequency with which refills must be given. Before deciding on such therapy one should consider carefully the advantages of alternating successive pneumothorax and of pneumothorax on one side and phrenic evulsion combined with scalenotomy on the other. A decision is often difficult to reach and involves considerable judgment based on past experience. Unfortunately, the results of phrenic evulsion and scalenotomy are not so certain as is that of successful collapse by pneumothorax and in times of emergency or when there is doubt, and time is an important element, the

Fig. 1—Advanced tuberculosis of right upper lobe.

Fig. 2—Complete collapse of right lung (same case as in figure 1). The diseased and healthy areas are equally collapsed and the lung is shrunken to a sausage-shaped mass lying close to the heart (shaded area in diagram). This type of therapy often results in a reactivation of a quiescent lesion in the contralateral lung and is happily becoming obsolete.

necessitating prompt intervention. Such patients can be helped materially by simultaneous bilateral pneumothorax. There need be no dyspnea or other signs of discomfort. In some instances the patients can be self-supporting while under treatment and within reasonable limits be permitted to lead normal active lives.

decision is often forced in favor of simultaneous bilateral pneumothorax in spite of its disadvantages. However, this treatment has a definite place in collapse therapy and greatly widens its usefulness.

ALTERNATING PNEUMOTHORAX

Alternating or successive pneumothorax as its name implies is the successive collapse of first one lung and then the other by artificial pneumothorax. Usually the first lung is not permitted to expand until it has been collapsed for a year or more. This type of therapy is especially indicated in patients who develop contralateral disease during pneumothorax treatment or who have bilateral disease equally distributed when first seen.

Alternating pneumothorax, introduced by Forlanini in 1911 is on the increase largely because therapeutic pneumothorax is now much more widely employed and because the majority of patients subjected to collapse therapy have considerable disease in both lungs. Some operators prefer alternating pneumothorax to simultaneous bilateral collapse as a safer and simpler procedure, and there is much to support such a view.

When alternating pneumothorax is indicated, the most involved side is collapsed first and a careful watch kept on the contralateral lung. Very often the untreated lung will improve with improvement in the collapsed lung, especially if the patient is kept in bed. Progression of disease in the untreated lung, however, may be a very serious complication and at times may require heroic measures, especially when the disease in the "good" lung is spreading rapidly and is accompanied by severe hemoptysis and high fever. In such

CASE 2—II S. A. man, aged 22, came under observation in February 1931, at which time he was acutely ill with tuberculosis of the right lung complicated by severe hemoptysis. Therapeutic pneumothorax was promptly instituted and a dramatic result obtained. The hemoptysis ceased, the cough and fever disappeared, and within two weeks the patient was well on the road to recovery. He gained rapidly in weight and within three months returned to active life. In January 1932, thirteen months after he first took ill, a series of colds

Fig 7—Selective collapse (same case as in figures 4, 5 and 6). On deep expiration the healthy lower lobe undergoes marked collapse and gives a striking illustration of the freedom of movement of the healthy part of the treated lung under selective collapse therapy.

Fig 8—Bilateral artificial pneumothorax. This patient is self supporting and leads a normal active life in a large city. The shaded area in the diagram represents the collapsed lung.

Fig 5—Selective collapse of right lung (same case as in figure 4). The diseased upper lobe is completely collapsed while the remainder of the lung which is healthy is permitted to function freely. (See figures 6 and 7.) This type of therapy greatly widens the indications for collapse therapy so that from 50 to 75 per cent of all tuberculous patients may enjoy its benefits. The shaded area in the diagram represents the collapsed lung.

Fig 6—Selective collapse (same case as in figures 4 and 5). On deep inspiration the healthy lower lobe expands almost to the chest wall while the diseased upper lobe remains collapsed as before.

cases the operator may be forced against his will to discontinue the

developed, with the sudden appearance of considerable disease in the "good" lung. This soon subsided under bed rest and the patient again was apparently on the road to recovery when severe hemoptysis developed, complicated by high temperature, Aug 2, 1932. This necessitated immediate intervention by pneumothorax. The hemoptysis ceased and the temperature returned to normal, and once more the patient's outlook on life brightened. For a short time simultaneous bilateral pneumothorax was maintained, but it was too severe a treatment for this patient. There was considerable dyspnea. Accordingly, the pneumothorax in the old or right side was discontinued and replaced by a phrenic evulsion, August 26. Twenty months has now passed and the patient's condition has steadily improved. He has no symptoms of tuberculosis, the sputum is negative and there has been no recurrence of the bleeding. Both lungs continue to clear, and there is no dyspnea. The patient has received a refill to the left lung every two weeks.

2104 Pine Street

**Eyestrain**—The connection of headache with eyestrain was first noted by medical writers in the latter part of the eighteenth century, but the morbid condition responsible for the majority of headaches was described by Donders (1818-1889) of Utrecht, who in 1850 was first to point out that inaccurate optical adjustment of the eyes causes not only diseases of the eye but many other conditions, including headache, nervousness, indigestion, etc. Donders however, like all persons engaged in pioneer work, did not realize the full clinical importance of his discovery. It was left to S. Weir Mitchell and William Thompson to place the anomalies of refraction on a firm scientific basis—perhaps one of the most important accomplishments in the realm of medicine and surgery—Gordon, B. L. Importance of Cephalalgia in Ocular Diagnosis, *Arch Ophth* 11 769 (May) 1934.

first pneumothorax and institute collapse in the "good" side. Case 2 is illustrative.

## SUPERIOR PULMONARY SULCUS TUMOR

FURTHER OBSERVATIONS, WITH REPORT OF TWO  
ADDITIONAL CASES

HAROLD W. JACOX, M.D.

ANN ARBOR, MICH.

In his most recent article dealing with the clinical entity of tumor characterized by pain, Horner's syndrome, destruction of bone, and atrophy of hand muscles, Pancoast<sup>1</sup> has said, "The name of 'superior pulmonary sulcus tumor' has been given it because this term implies its approximate location and a lack of origin from lung, pleura, ribs or mediastinum. It is possible that this new designation may be changed again with a better knowledge of the histopathology of the growth." Opportunity to examine autopsy material from a case of this sort has convinced me that, at least in this instance, the tumor arose from the mucosa of the terminal bronchioles in the apex of the lung, and that the name "primary carcinoma of the pulmonary apex" might be appropriate. In another case presenting the same clinical manifestations I have been studying the effects of prolonged, fractionated short wavelength roentgen therapy.

### REPORT OF CASES

**CASE 1—Clinical History**—W. C., a white man, aged 55 American, a bottler, referred to the medical department of the University Hospital by Dr. F. S. Baird of Bay City,

Fig. 1 (case 1)—Shoulder showing destruction of the posterior half of the right first rib.

Mich., July 25, 1933, complained chiefly of pain in the right arm and shoulder. The present illness dated from the previous October, approximately ten months before, when he first noticed a dull aching in the muscles on the inner aspect of the right elbow. The pain had become progressively worse since its

onset, was more or less constant and was more severe at night. It was aggravated by motion and gradually involved the muscles of the shoulder girdle, accompanied by weakness and areas of numbness. The usual methods of treatment failed to give relief, except that hot applications occasionally produced some benefit. Five months before entrance the patient had all his teeth extracted in an effort to remove the cause of the pain, without avail. At times when the pain was very severe as much as 2 grains (0.13 Gm.) of morphine would not relieve him. Since the onset of the present illness he lost 15 pounds (6.8 Kg.), which represented about 8 per cent of his total body weight. General weakness and malaise also developed during this time. The past history was unimportant except for an illness that had been diagnosed as "pleural pneumonia" fifteen years before, for many years he had had a morning cough productive of whitish phlegm. For an indefinite period he had slight dyspnea and palpitation on exertion and a sense of constriction at the base of the neck.

Fig. 2 (case 1)—Chest demonstrating definite growth in the right apex.

Seven years before admission he had an attack of what was diagnosed angina pectoris, but there had been no similar symptoms since that time. There had never been any hemoptysis. The family history was entirely irrelevant.

**Physical Examination**—The following relevant data were obtained on admission. The skin over the right lateral thorax showed areas of hyperpigmentation due to applications of a hot water bottle. There were no other skin changes. There was a typical Claude Bernard-Horner's syndrome on the right with ptosis, contracted pupil and anhidrosis. All the muscles of the right shoulder girdle, arm and forearm showed considerable atrophy, and fibrillary tremors. Tenderness in the right axilla could be elicited by deep pressure. The biceps, triceps, radial and ulnar periosteal reflexes were hyperactive, and there was definite weakness of the muscles of the right arm. There were no definite objective sensory disturbances except hyperesthesia of the inner aspect of the right arm. The possibilities suggested by the neurologic examination were, first, progressive spinal muscular atrophy, second, amyotrophic lateral sclerosis, and, third, a cervical rib. The opinions of the orthopedic surgeon and neurosurgeon were that the pain was radiculitis and that there was a definite tumor mass that was probably a neurofibroma and did not arise from bone. The systolic blood pressure was 130, the diastolic 80, with only slight variations on several readings. There was slight clubbing of the fingers. Urinalysis was repeatedly negative. The hemoglobin was 75 per cent (Sahli), the red blood cell count was 3,650,000 and the white blood cell count was 11,300 per cubic millimeter, with a normal differential formula. Routine Kahn tests of the blood and spinal fluid were negative. No sputum could be obtained for examination.

**Röntgen Examination**—On admission, a study of the right shoulder and the cervical and dorsal portions of the spine demonstrated a dense infiltrative process throughout the apex of the right lung. The vertebral portion of the right first rib was almost completely destroyed (fig. 1). All other structures appeared normal. The possibilities of a primary bone tumor of the rib, a sarcomatous lesion of the pleura at the apex and pulmonary tuberculosis with rib involvement were considered. Examination of the chest the next day (fig. 2) seemed to indicate the last of these. From an additional chest examination four days later a provisional diagnosis of right superior pulmonary sulcus tumor was made.

Read before the Detroit Roentgen Ray and Radium Society April 5, 1934.

From the Department of Roentgenology, University of Michigan Medical School.  
1. Pancoast, H. K., Superior Pulmonary Sulcus Tumor. *Chairman's Address*, J. A. M. A. 99: 1391 (Oct. 22) 1932.

**Clinical Course**—A biopsy of a hard, immobile tumor mass behind the lower lateral border of the right sternocleidomastoid muscle was taken, August 2. The pathologic diagnosis was as follows: Blood vessel, fascia and small nerve showing diffuse infiltration with carcinoma. Carcinoma spreads diffusely. Shows no evidence of glandular architecture. Dr C V Weller gave the verbal opinion at this time that the neoplasm might be of bronchial cleft origin.

At consultation I expressed the belief that the only possible benefit in the light of present knowledge was by a combination of high voltage roentgen therapy followed by radium needle implantation after surgical exposure, which would constitute a thorough test of irradiation.

The patient stated that the pain was so severe that he did not care what risk was taken to relieve him. He readily consented to operation and August 11, was transferred to the department of thoracic surgery for this. His vital capacity was found to be 3,400 cc. Under local and secondary nitrous oxide anesthesia the right first rib was removed with the idea of implanting radium needles in the tumor. A stony hard tumor surrounded the articular portion of this rib, grossly invading it and infiltrating into the posterior triangle of the neck. There was a tongue-like extension of the tumor downward, separating it from the lateral surfaces of the bodies of the upper thoracic vertebrae. It was found that the roots of the brachial plexus were deeply embedded within the tumor mass and that the bony destruction was considerably greater than that revealed by the roentgen examination. At this point the patient's pulse became weak and rapid and the blood pressure, normal at the beginning of the operation, dropped to zero. Hemorrhage, developing in the surgical field, could not be completely controlled, and in spite of all efforts to revive the patient he died shortly from shock. The main mass of the tumor had been removed and the pathologic diagnosis was as follows: "Carcinoma, largely scirrhous in type, invading connective tissue, fascia, nerves, sheaths of blood vessels and voluntary muscle. The adherent lung was also infiltrated with the same carcinoma and to the same degree, as far as could be determined. The bone marrow of the first rib was largely replaced by carcinoma." Permission for a necropsy was obtained.

Fig 3 (case 1)—Section of autopsy material with predominantly squamous but some glandular characteristics in the same high power field from the right apex.

**Necropsy—Gross Anatomy** The surgical incision was 19 cm long, curving from the posterior cervical triangle backward and around the superior angle of the scapula, and downward to approximately the level of the fifth thoracic spine. The upper third of the upper lobe of the right lung had been resected. There was extensive neoplastic invasion of the soft tissues on the right side of the neck extending to the level of the fifth cervical vertebra. This neoplasm was firm white and glistening in character. It was situated entirely lateral to the internal carotid on the right side and medial to the skin of

the neck. It was patchy in appearance, showing scattered nodules. The left lung and the remainder of the right were perfectly normal. The bronchi were thoroughly explored and showed no evidence of neoplasm arising in them. The greater portion of the right subclavian artery was surrounded by a neoplasm, and all the large nerve trunks were surrounded and compressed by neoplastic tissue. There was hemorrhage into the tissues in the region of the junction of the subclavian and vertebral arteries.

The left suprarenal proper was approximately of normal size. A portion was replaced by glistening, white tissue and

Fig 4 (case 1)—Section of autopsy material with predominantly squamous but some glandular characteristics in the same high power field from suprarenal metastases.

was completely surrounded by characteristic neoplastic tissue. This mass measured 4 cm in diameter. The right suprarenal showed a mass of tissue exactly similar to that on the left side. On section there was exposed only a thin layer of suprarenal tissue about the periphery of this mass of neoplasm. The kidneys were entirely normal and showed no malignant changes.

**Microscopic Anatomy** There was no evidence of metastases to the central nervous system. The remaining portion of the right upper lobe of the lung showed a well advanced carcinoma. This developed as an adenocarcinoma, capable of forming mucin, but tended to become rapidly undifferentiated and medullary (fig 3). The first thoracic vertebra showed extensive infiltration of the surrounding tissues, periosteum and bone itself (after decalcification) by scirrhous adenocarcinoma. The suprarenals showed bilateral metastatic medullary adenocarcinoma (fig 4). The regional and distant lymph nodes showed no metastases.

Dr C V Weller made the following comment: "Clinically this tumor falls in the group designated by Pancoast as 'superior pulmonary sulcus tumor'. In any clinical compilation it can be included in that group. At present, however, this term does not denote a pathologic entity. Since this carcinoma is an adenocarcinoma, it could not have arisen, so far as we know, in bronchial cleft remains. Since it is mucin forming, the primary cannot be referred to the suprarenals. Both by direct evidence and by exclusion one is forced to the conclusion that this is of bronchogenic origin."

**CASE 2—Clinical History**—S P, a man, aged 44, American, a chauffeur, referred to the Department of Neurosurgery of the University Hospital by Dr F G Maurer of Lima, Ohio, Nov 26, 1933, complained chiefly of severe pain in the left arm, shoulder and upper posterior portion of the chest of three or four weeks' duration. The pain radiated down the left arm generally to the inner aspect of the elbow. He had also noticed increased warmth of the entire left upper extremity and the left side of the face with absence of sweating over this area. The pain was accentuated by cold but had been relieved somewhat by heat and narcotics. Five or six years before admission after he had been driving in the wind, a left facial

palsy developed, which had improved. There had been an injury over the left eye a few years before, following which there was a drooping of the left upper eyelid. This had increased, however, since the patient had noticed the pain in the arm. Three or four years before admission he had had antisyphilitic therapy for a penile sore. He had been told that on no occasion was his blood or spinal fluid positive. He had had a hacking nonproductive cough for many years but never any hemoptysis. Since the onset of the present illness he had lost 10 pounds (4.5 Kg.), or approximately 5 per cent of his total body weight. The family history was not relevant.

**Physical Examination**—The following pertinent data were obtained. There was a typical Horner's syndrome on the left side. The left side of the face, left hand, shoulder and axilla showed anhidrosis, and these areas were warmer than the corresponding areas on the right. This was confirmed by skin temperature readings which showed a difference of 3 degrees

Fig 5 (case 2)—Chest showing similarity to figure 1 but in opposite apex

C between the hands. Neurologic examination showed, in addition, a well sustained nystagmus on lateral deviation to either side, and there was some diminution of convergence on the right. The left angle of the mouth was less well retracted than the right. Biceps and triceps reflexes were present, slightly diminished, but about equal. The abdominal reflexes were diminished, and the Achilles jerks were diminished bilaterally. Vibratory sense was diminished on the left and almost absent on the right. There was some ataxia on the heel to knee to toe test, and some swaying in the Romberg position with the eyes closed. Sensory examination showed glove and stocking hypalgesia bilaterally but no other neurologic changes. The impression obtained from the neurologic examination was, first that of early tabes dorsalis, second, questionable thoracic neoplasm or, an unlikely possibility, spinal cord tumor. There was a palm-shaped area of definite blanching of the skin overlying the left scapula, measuring 8 by 10 cm., with sharply demarcated borders. There was definite clubbing of the fingers. The blood pressure was 130 systolic and 85 diastolic and varied but little on repeated determinations. Urinalysis on entrance and on repeated examinations was negative. Blood studies were entirely normal. Routine Kahn tests of the blood and spinal fluid proved to be negative. A dextrose tolerance test was not abnormal. No sputum could be obtained for examination.

**Röntgen Examination**—Routine studies of the chest and spine demonstrated a soft tissue mass with fairly sharply defined outer margins completely filling the arc of the first rib in the left apex (fig 5). The mass seemed to be more posterior than anterior and there was some stripping of the pleura. A neoplasm of the posterior left thoracic apex was reported. Films of the abdomen showed no abnormal calcifications. Special stereoscopic detail studies of both apices showed definite loss of bone substance in the neck and head of the left second rib and the diagnosis of left superior pulmonary sulcus tumor was made.

**Clinical Course**—The patient was referred to Dr. F. A. Collier of the surgery department for his opinion regarding therapy, and his reply was as follows: "I feel that the diagnosis is fairly clear. As surgical excision is impossible and as x-ray is the only treatment I do not see that a biopsy is worth while." Consequently the patient received daily treatments with 200 roentgens (measured in air), effective wavelength 0.15 angstrom unit (200 kilovolt peak, 0.5 mm. or

copper plus 1 mm. of aluminum), cross-firing the left supraclavicular region from front and back through each of two portals measuring 15 by 15 cm. (fig 6). Each portal received 4,200 roentgens within a period of twenty-five days from December 5 to 30 inclusive, or a grand total of 8,400 roentgens. During this time the pain was controlled by sedatives or narcotics when needed. The pain became less intense during the course of treatments and on completion it was practically gone, there being merely superficial pain present. The skin temperature changes were disappearing at the time of his discharge, and chest films showed a definite decrease in infiltration in the left apex. The patient was discharged with the advice that if at any time there was exacerbation of the pain chordotomy would be performed.

The patient returned for check-up examination three and one-half months from his previous admission, on March 13, 1934. He had completely recovered from the effects of treatment such as loss of voice and appetite, and the skin which had been denuded had healed. He showed improvement roentgenographically (fig 7) and clinically, but there was no change in the appearance of the rib destruction. Neurologic examination revealed persistent sympathetic paralysis, but all symptoms and signs including the severe pain were less noticeable. The neurosurgeon's opinion was that high cervical chordotomy should not be performed because the patient was getting along so well. No treatment was given and he was discharged with the same advice as before. Ten days later he returned, stating that for the past several days he had attacks of pain in the left arm and upper left side of the chest exactly similar to those which he first experienced. There was some relief with large doses of narcotics.

Fig 6 (case 2)—Appearance before treatment showing Horner's syndrome with size and location of roentgen portals of entry (arrow represents angulation of central ray)

March 24, a high cervical (third) chordotomy was done with good immediate postoperative condition, and the pain was entirely relieved. On the second postoperative day while smoking he received a small burn of the left middle finger, owing to the loss of temperature sense. On the twelfth postoperative day the patient was entirely free from pain and was discharged. The wound half of which was in the field of irradiation was well healed throughout. The relatives were

told that no further radiation therapy would be given and that the prognosis was grave. The possibility that the pain might return (because about 10 per cent of the pain fibers travel up the homolateral side) was also mentioned.

#### COMMENT

The similarity of the two cases here reported is readily apparent. Even when the symptoms were of less than one month's duration, as in the second case, I believe that they fulfil all the criteria of the clinical entity previously described as superior pulmonary sulcus tumor. The clinical features of this condition represent a definite and striking syndrome quite different from that of the usual primary malignant growths of the lung.<sup>2</sup> The apical chest tumors reported by Henderson<sup>3</sup> do not fall into this particular category. Neither do large lesions of the upper lobe, which may also produce Horner's syndrome.

Fig 7 (case 2)—Follow up examination three and one half months later demonstrating reduction in infiltration coincident with clinical improvement.

To demonstrate the protean clinical aspect of a carcinoma originating primarily in the lung, Fried<sup>4</sup> describes the case in a man, aged 41, a freight agent, which probably belongs in this group. The onset was with sharp stabbing pain in the right shoulder radiating down the arm with atrophy of muscles, clubbed fingers and Horner's syndrome. The first impression was that the patient had syringomyelia. On subsequent visits the symptoms increased and the diagnosis of a malignant neoplasm was evident. Death occurred three years and eight months from the onset of the first symptoms. At necropsy a primary carcinoma of the apex of the right lung with involvement of the sixth and seventh cervical and first and second thoracic vertebrae was found, the first, second and third ribs were also invaded, and there were metastases to the liver, kidneys, suprarenals, heart, lymph nodes, sigmoid colon, stomach, pancreas, mediastinal lymph nodes, subcutaneous tissue and skull. This case may represent the natural course and duration of the disease, although Pancoast's patients did not live much more than a year.

Tobias<sup>5</sup> has described an "apicocostovertebral doloroso" syndrome with clinical and radiographic evidence of a tumor of the apex associated with intense radicular pain and sympathetic paralysis. He found this syndrome in one case of primary carcinoma of the apex of the lung without biopsy or autopsy and also observed it three times in metastatic or extensive lesions in this

region. Pancoast grants the possibility that the lesions in cases 6 and 7 of his group may be metastases from carcinoma of the cervix uteri. I have seen similar cases with metastases in the apex but without the complete clinical and radiologic manifestations.

Robertson<sup>6</sup> feels that the majority of so-called primary malignant tumors of the pleura are in reality metastases or extensions from primary lung carcinomas. Surely his belief is substantiated by the observations in my first case. Not until autopsy material became available were the glandular and mucin-producing qualities of this tumor recognized. Judged on the basis of the biopsy alone, the diagnosis must have been squamous cell carcinoma. Metastases to the suprarenals only are occasionally found in primary bronchogenic carcinoma. This may account for the peculiar type of death which Pancoast described in his patients.

#### CONCLUSIONS

1 Evidence is presented supporting the view that superior pulmonary sulcus tumor is an atypical form of primary bronchogenic carcinoma.

2 A modification of Coutard's method of intensive deep roentgen therapy failed to control the symptoms of this disease.

3 Chordotomy should be considered as a valuable palliative procedure.

4 Incidentally, wound healing was not retarded by intensive roentgen therapy.

## THE DIFFERENTIAL DIAGNOSIS OF HYPERPARATHYROIDISM

ALEXANDER B. GUTMAN, MD

PAUL C. SWENSON, MD

AND

W. BARCLAY PARSONS, MD

NEW YORK

Excessive parathyroid secretion, such as occurs with parathyroid adenomas, causes a drain of lime salts from the body resulting in skeletal changes classified as Recklinghausen's disease or generalized osteitis fibrosa cystica. The negative calcium and phosphorus balance is commonly associated with hypercalcaemia, hypercalcaemia and hypophosphatemia and with skeletal, renal and gastro-intestinal symptoms that together constitute the classic form of hyperparathyroidism. The differentiation of this disease from others involving the bones is important because surgical removal of parathyroid adenomas is usually followed by extraordinary improvement if carried out before advanced skeletal deformities or renal impairment preclude complete restitution of the patient. The differential diagnosis of hyperparathyroidism may be difficult, however. The onset of the disease is usually insidious, the early manifestations are extremely varied, aberrations from the classic picture are common and the most characteristic features may be closely simulated by other diseases involving the bones.

In this study, the problems relating to early recognition of hyperparathyroidism are particularly

emphasized<sup>1</sup> Four new proved cases are presented The data in 115 proved cases in the literature<sup>2</sup> have been analyzed to indicate the incidence of initial presenting symptoms and their relative diagnostic significance The usefulness and limitations of laboratory procedures in the diagnosis of suspected cases are considered

#### PRESENTATION OF CASES

Our first case conforms to the classic picture of the disease Our second case, in which skeletal deformities and renal damage were more marked, exhibited an interesting fall in the initially high serum calcium coincident with the onset of acute uremia Both patients did very well after removal of a parathyroid adenoma We are indebted to Dr Allen O Whipple for permission to add a third case, under observation for sixteen years A parathyroid adenoma was removed else-

his past history were irrelevant to the present illness, which began in 1931 with "rheumatism" in both arms In January 1932, while throwing a ball, he fractured the right humerus, in which a roentgenogram disclosed a cyst The fracture healed in eight weeks, but the pain in the arms persisted Loss of 30 pounds (13.6 Kg) and weakness developed, with slow response to cod liver oil and calcium lactate Dry mouth, polydipsia and polyuria were first noted about this time In July 1932, dull pain in the lower part of the back, the right hip and leg, with a lump, developed Roentgenograms disclosed cysts in the pelvic bones Six months later, after a slight trauma, he noted a painless bony swelling just below the right knee About this time he found that for the first time in fourteen years he needed a larger hat size In May 1933 he complained of nervousness, exertional dyspnea and transitory sticking pain in the chest Episodes of nausea and vomiting set in, and constipation became more pronounced After spending the better part of two months in bed, he sought admission

When first seen, he appeared chronically ill, anxious and somewhat confused mentally There were no skeletal deformities except shortening and limitation of flexion of the right arm due to malunion of the old fracture A nontender bony swelling could be palpated along the anterior surface of the right tibia 6 cm below the knee The teeth were missing except for markedly carious lower incisors A questionable resistance could be felt near the lower pole of the thyroid gland on the right side No other abnormalities were noted Laboratory examination on admission showed erythrocytes, 3,760,000, leukocytes, 15,200, with 76 per cent neutrophils, hemoglobin, 72 per cent (Sahl), blood Wassermann test, negative, a faint trace of albumin but no sugar or Bence-Jones protein in the urine The phenolsulphonphthalein excretion was normal The basal metabolism rate was +3 per cent The QT interval in the electrocardiogram was 0.36 second with a heart rate of 80 The results of chemical examination of the blood are recorded in table 1 Roentgenograms of the skeleton revealed a generalized osteitis fibrosa cystica, with moderate decalcification and cysts in the pelvis, both tibias, the left femur, five ribs and several metatarsal bones (fig 1) The skull showed characteristic fine mottling There was a shadow of calcium density in the abdomen suggesting calcification in a horseshoe kidney (fig 2) Balance studies showed increased excretion of both calcium and phosphorus in the urine The patient required an intake of about 1 Gm of calcium a day to maintain calcium equilibrium (fig 3)

Exploratory operation, August 17 (W B P), disclosed a parathyroid tumor partially embedded in the posterior aspect of the lower part of the right thyroid lobe, which was removed Further inspection revealed no other masses August 20, tingling developed in the toes, fingers and tip of the nose with occasional irritability, relieved by administration of calcium chloride and parathyroid extract (table 1) The Chvostek and Trousseau signs were always negative August 28, the patient felt so well that he was discharged Four months after operation he was working hard, had gained 30 pounds and felt very well Slight pain in the right hip was still present after walking Roentgenograms showed definite signs of recalcification, most pronounced in the skull, where the grainy appearance of the vault was definitely less marked Eight months after operation his condition was excellent Results of postoperative blood analyses are shown in table 1

The tumor was an encapsulated, soft, lobulated, yellowish gray mass measuring 27 by 16 by 10 cm and weighing 35 Gm Microscopic examination (Dr F M Smith) revealed a parathyroid adenoma composed chiefly of syncytium-like groups of large cells containing large oval darkly stained nuclei with abundant pale granular cytoplasm, closely packed or arranged in small alveoli enclosing pink-staining colloid-like material A few small nests of water-clear and rose-red cells were seen, but no oxyphile cells of Welch

CASE 2—M W an Irish housewife aged 53 was referred by Dr F R Bailey June 28, 1932 for admission as a probable case of hyperparathyroidism There was no history of familial or childhood bone disease In 1913 during her third pregnancy, and again in 1917 renal colic developed, relieved by

Fig 1 (case 1)—Right tibia (A) before and (B) eight months after operation showing cystic areas filled in

where, but the patient subsequently died We are indebted to Dr Dana W Atchley for permission to report a fourth case, interesting because of polycystic kidneys and recurrent attacks of renal colic for twenty-three years, terminating in uremia associated with hyperphosphatemia and normal serum calcium Two parathyroid adenomas were found at autopsy

CASE 1—C G, an American salesman, aged 34, admitted, July 10, 1933, complained of constant aching in the right hip, loss of 20 pounds (9.1 Kg) and weakness His familial and

<sup>2</sup> This series includes only cases of parathyroid overactivity in which one or more parathyroid adenomas were found at operation or autopsy A bibliography is included in the reprints of this article

removal of a calculus from the right kidney. But for three months thereafter she suffered headache, anorexia, nausea and vomiting, with loss of weight. In 1922 these symptoms recurred, together with nocturia and flaky sediment in the urine. Repeated cystoscopic examinations suggested pyelonephritis, and the right kidney was removed. The surgical specimen showed fibrotic degeneration of many glomeruli, hyalinization of many tubules and several areas of interstitial

Fig 2 (case 1)—Abdomen, showing calcification within the substance of a horseshoe kidney

calcification. The diagnosis of chronic nephritis was made. At that time bone deformities were not apparent. The blood pressure was 155 systolic and 95 diastolic, the blood urea nitrogen was 25 mg per hundred cubic centimeters, the blood uric acid was 6.3 mg, and the phenolsulphonphthalein excretion was 30 per cent. In 1924 she complained of "rheumatic" pains in the feet and arms and a loss of 18 pounds (8.2 Kg). A diagnosis of anxiety neurosis was made. In 1928, after slight trauma, she ruptured the right quadriceps tendon, which was found by x-rays to be partially calcified. She again complained of vague diffuse "rheumatic" pains. In 1931 increasing curvature of the spine, loss of height, and clubbing of the fingers were noted. In June 1932 she reported a loss of 15 pounds (6.8 Kg), hoarseness, weakness and severe pain between the shoulder blades. A roentgen study of the chest did not show any pulmonary pathologic changes but Dr Ross Golden observed decalcification of the humeri with cysts suggesting hyperparathyroidism. Further roentgen examination disclosed generalized decalcification of bone, with cysts in the left femur and characteristic grainy mottling of the skull (Fig 4). The serum calcium was elevated (table 1).

On admission, the patient appeared pale and emaciated. She was almost aphonic. There was an extreme rounded dorsal kyphosis, marked deformity of the thoracic cage and expansion of the terminal phalanges. No bowing of the legs, swellings or tenderness of the bones were noted. Her height, normally 68 inches (173 cm), was now 58 inches (147 cm). A small mass was palpable at the right lower pole of the thyroid gland. Laboratory examination on admission showed blood Wassermann test, negative erythrocytes, 4,160,000, leukocytes, 7,350 with 70 per cent neutrophils, hemoglobin, 87 per cent (Sahli). A faint trace of albumin was present in the urine with many leukocytes in the sediment. The basal metabolic rate was +22 per cent. Investigation of the cause of the aphonia July 5, by direct laryngoscopy under tribrom-ethanol anesthesia revealed only an edema of the mucous membranes. Recovery from anesthesia was slow. Vomiting and drowsiness persisted and blood studies (table 1) indicated increasing renal insufficiency. The phenolsulphonphthalein excretion was 10 per cent and the blood pressure 103 systolic, 85 diastolic. July 20, how-

ever, vomiting ceased and she appeared brighter. Her weight, however, had fallen to 76 pounds (34.5 Kg) and the blood pressure to 75 systolic and 50 diastolic. July 28, exploration (W B P) revealed a considerably enlarged lower right parathyroid gland, which was removed. August 3 (table 1), positive Trousseau and Chvostek signs were elicited and the patient complained of paresthesias. These responded to intravenous administration of calcium gluconate and parathyroid extract, but August 5 marked euphoria, irritability and irrationality developed, culminating in outbreaks of violence. As the serum calcium values rose, these episodes ceased. At the time of her discharge, September 14, her weight was 87 pounds (39.5 Kg) and her general condition was much improved. She could walk slowly but felt some ache in the bones after standing for long periods. Roentgenograms of the bones showed striking recalcification (figs 5 and 6). Twenty months after operation her condition continued to be very satisfactory.

The tumor was described (Dr A P Stout) as a bilobed, partially cystic, yellowish pink mass, 3.0 by 2.0 by 0.8 cm in size, and 4.5 Gm in weight. Microscopic examination revealed a parathyroid adenoma showing a marked proliferation of the water-clear and rose-red cells with large syncytium-like cell groups. Small scattered islands of the two cell types were also seen.

CASE 3—E M, an unmarried Scotch housemaid, aged 35, was admitted in 1916 because of a painless bony swelling of the right lower jaw of two years' duration. A partial osteotomy of the right mandible was done. On recurrence of the bony swelling in 1920 the jaw was resected. The pathologic diagnosis of the surgical specimen was giant cell sarcoma. All this time her general condition remained excellent except for transitory pains in the feet and right hip, attributed to flat feet. In 1924 she noted pain over the left clavicle, thought to be due to pleurisy or neuritis. In 1926 a definite tender swelling of the clavicle appeared with pain so marked that she was unable to use the left arm. There was also some weakness and slight soreness of the knees and thighs, but there were no general complaints. She had gained 20 pounds (9.1 Kg) since the resection of the jaw.

On physical examination the patient did not appear acutely or chronically ill. Roentgenograms showed a multilocular cyst in the left clavicle, multiple areas of rarefaction in many ribs,

Fig 3 (cases 1, 5 and 6).—Normal figures calculated from data of Farquharson, Salter and Aub (J Clin Investigation 10:251 [June] 1931). Patients 1, 5 and 6 were studied in the metabolism ward under the supervision of a specially trained personnel. Neutral ash diets were prepared; the calcium and phosphorus content being determined by analysis of aliquots of three day periods. Salt and water intake were controlled. The patients were allowed out of bed three hours daily.

in the right clavicle and in the left fibula and tibia. A moth-eaten decalcification of the terminal phalanges was seen in both hands. The skull showed a peculiar soft mottling with widening of the tables attributed to Paget's disease. A biopsy of the area in the left clavicle showed "an unusual type of

giant cell sarcoma," with considerable osteoid tissue. Laboratory examinations revealed a mild secondary anemia, serum calcium, 115 and again 120 mg per hundred cubic centimeters, serum inorganic phosphorus, 25 mg, blood urea nitrogen, 17 mg, and phenolsulphonphthalein excretion, 50 per cent. After treatment with colloidal lead injections, she recovered the use of her left arm and was able to resume work.

Fig 4 (case 2)—Lateral view of skull before operation

Roentgenograms of the skeleton in 1927 showed new cysts in the left femur and in both patellas. The diagnosis of fibrocystic disease was made by Dr. Ross Golden. In 1928 she returned to Scotland, where she was under the care of Dr. Archibald Young. She continued to feel quite well and maintained her weight and strength. In February, 1932 she suffered a pathologic fracture of the leg. In May of that year a parathyroid adenoma was removed, but the patient subsequently succumbed.

**CASE 4**—N. P., an unmarried American woman, aged 60 a clerk, was referred from the Neurological Institute, May 29, 1933, because of abdominal pain and generalized pruritus. There was a familial history of hypertension. One sister had polycystic kidneys. In 1910, after an attack of colic, a celiotomy disclosed numerous cysts extending from the right kidney to the ovary, which were removed. She had frequent attacks of renal colic since then and passed many stones. In spite of this and numerous minor complaints, she was able to carry on her work. In 1931 she was admitted because of progressive loss of function of the legs, symptoms of cystitis and continued attacks of renal colic. Roentgen examination revealed bilateral polycystic kidneys. In 1932 she complained for the first time, of vague "arthritic" pains and numbness in the extremities. In 1932 she fractured both ischia in an accident, requiring hospitalization for almost a year. In 1933 she developed pruritus, nausea, vomiting and abdominal colic suggestive of biliary stone. She lost 12 pounds (5.4 Kg) in this period. Constipation, present for years, became more marked.

When first seen she walked with a limp using a cane. There was a marked kyphoscoliosis of the lower dorsal and lumbar spine with flaring of the lower ribs. The fingers were clubbed with peculiar transverse indentations of the nails. The breath was definitely urinous and the deep reflexes were hyperactive. The arteries were markedly sclerotic. There was no demonstrable tumor in the neck. The enlarged polycystic kidneys were easily palpable. The blood pressure was 130 systolic and 70 diastolic. The erythrocytes numbered 3,300,000 and the leukocytes 6,100 with 69 per cent neutrophils. The blood Wassermann test was negative. The basal metabolic rate was  $\pm 5$  per cent. A trace of albumin was consistently present in the urine with occasional leukocytes in the sediment. The phenolsulphonphthalein excretion on two occasions

was 0 per cent. The blood urea nitrogen was 100 mg per hundred cubic centimeters, and the blood creatinine 33 mg. Roentgen study of the biliary tract failed to show filling of the gallbladder, but no calculi were visualized. Marked decalcification of the vertebrae and a contracted pelvic inlet were noted. Decalcification of the ribs and fine mottling of the skull were described by Dr. Ross Golden as consistent with hyperparathyroidism. The serum calcium was found to be 97 mg per hundred cubic centimeters and again 102 mg, with elevation of the serum inorganic phosphorus to 84 mg per hundred cubic centimeters due to the renal insufficiency. The serum phosphatase was 273 Bodansky units.

Opinion was divided as to whether the skeletal changes were manifestations of a primary parathyroid adenoma or hyperparathyroidism secondary to chronic renal insufficiency due to the presumably congenital polycystic kidneys. In retrospect it is felt that prompt surgical intervention was desirable and that such cases should be explored in spite of renal insufficiency (case 2). She was referred back to the Neurological Institute, where she received radiotherapy to the parathyroid region. The deformity of the spine increased, a swelling of the left maxilla and temporal bone appeared, she became bedfast, grew progressively weaker and finally died, Sept. 15, 1933. We are indebted to Dr. Abner Wolf for the autopsy report, which disclosed a tumor of the right upper parathyroid gland, 2 cm in diameter, partially embedded in the right lobe of the thyroid gland, and another, in part cystic, tumor of the right lower parathyroid gland 15 by 0.7 by 0.4 cm. Histologically eosinophilic cells predominated. The bones were remarkably soft and pliable, many cystic. The skull was thickened and the outer table irregular. A fracture of the left femur was present. The liver contained several cysts. The kidneys were greatly enlarged, containing innumerable large and small cysts with partially calcified walls. Microscopic examination showed little functioning renal tissue, marked interstitial fibrosis with areas of calcification, fibrosis of many glomeruli and dilatation of the tubules.

#### CLINICAL PICTURE OF HYPERPARATHYROIDISM

As in all previous studies,<sup>3</sup> our data on 115 published proved cases of hyperparathyroidism indicate that the

Fig 5 (case 2)—Lateral view of skull nine months after operation

disease occurs more frequently in females (eighty-six females twenty-nine males) and, while widely distributed as to age incidence occurs most frequently in middle life (table 2). The course of the disease is usually measured in years rarely in months.

The disease begins most frequently with pain (table 3), usually a dull ache in the lower part of the back, legs or arms, intensified by exercise and often associated with stiffness of the joints. The pain, usually

\* The authors are indebted to Dr Aaron Bodansky for these values and for many helpful suggestions. The phosphatase activity of serum of normal adults as determined by his method varies from 1 to 4 units.

regarded as rheumatic, arthritic or neuritic, tends to become more diffuse and intense. It may be so marked as to require the constant use of narcotics, and sometimes, when the patient has to be moved, the use of anesthetics. Bone tenderness, localized at first, is common and may eventually become generalized. Muscle weakness with hypotonia may be so marked as to simulate Addison's disease, myasthenia gravis or progressive muscle dystrophy, when associated with muscle wasting. Localized bone swellings, solitary and painless at first but multiple and tender later on, are most common in the jaws but occur frequently in the tibia, phalanges or elsewhere, particularly after slight trauma. They may appear years before the onset of general symptoms and may be difficult to differentiate pathologically from sarcoma or from focal osteitis fibrosa.

Pathologic fractures, particularly of the extremities and ribs, are often the immediate cause of hospital admission. The incidence of fractures increases as decalcification progresses, until the patients are reduced to such a state that turning in bed or violent coughing may result in bone fracture. Nonunion and malunion are common, often resulting in impairment of function and deformities. Deformities of all types occur (curvature of the spine, collapse of the thoracic cage or pelvis, symmetrical or asymmetrical enlargement of the head, lateral or anterior bowing of the legs, coxa vara and genu valgum) sometimes with loss of height and bizarre mutilation of the extremities. The deformities may simulate those seen in osteomalacia or in Paget's disease.

Disturbances of gait of the waddling type or limp may develop relatively early and become progressively

4 Bodansky, Aaron. Determination of Serum Phosphatase. *J Biol Chem* 101: 93 (June) 1933.

worse, more than a third of the patients in this series ultimately becoming bedfast. Totally incapacitated, wracked with pain, grossly deformed, in constant danger of recurring fractures, such patients emphasize the importance of diagnosis and removal of parathyroid adenomas early in the disease.

Polyuria and polydipsia may be so marked as to suggest diabetes insipidus. Renal colic was the predominant symptom in about 10 per cent of the cases. Bone changes may develop relatively late in patients with nephrolithiasis, pyelonephritis and chronic nephritis with serious impairment of renal function. Episodes of intractable nausea and vomiting may appear suddenly and persist for weeks or months. Anorexia and stubborn constipation are common and may be presenting symptoms. In six cases, sharp pain in the abdomen appeared. The gastro-intestinal symptoms may so dominate the picture as to suggest duodenal ulcer or acute appendicitis. Most patients lose weight, and in one-fourth this was a major complaint. Moderate secondary anemia is common. Nervousness, tachycardia and other symptoms have been described. A tumor in the neck could be palpated definitely in less than 10 per cent of the cases, a palpable mass sometimes proving to be a thyroid adenoma.

It would appear that these apparently diverse symptoms may be referred for the most part to the same causal mechanism—increased parathyroid secretion. Bone lesions similar to those occurring in clinical hyperparathyroidism have been produced in animals by injections of parathyroid extract.<sup>5</sup> Vomiting, anorexia, failure of kidney function and death in uremia result from parathyroid extract overdosage in acute animal

received excessive doses of parathyroid extract. Almost without exception, removal of parathyroid adenomas in cases of hyperparathyroidism resulted in abrupt cessation of nausea and vomiting in patients who had exhibited these symptoms, sometimes for months. The gastro-intestinal symptoms, therefore, and, to a certain degree, the acute renal symptoms appear to be toxic manifestations of acute hyperparathyroidism.<sup>8</sup> Polydipsia and polyuria presumably reflect the water loss associated with increased urinary excretion of calcium ("calcium diabetes"),<sup>9</sup> which also favors the formation of urinary calculi. Secondary infection of the urinary tract and serious impairment of kidney function are common complications and, not infrequently, the ultimate cause of death, sometimes even after acute symptoms are relieved by removal of a parathyroid adenoma. Postoperative investigation of renal function is, therefore, important (case 1).

#### ROENTGENOLOGIC EVIDENCE OF HYPERPARATHYROIDISM

The importance of a roentgen examination is indicated by the large proportion of cases in which suspi-

structures. Altered trabecular structure and cyst formation are often found in the metacarpals. In early stages of the disease, decalcification may not be striking. Cysts may be entirely absent or present in only one or two bones.

Softening of the skeletal structure results in deformities, particularly of the spine, pelvis and thoracic cage. In the long bones, pathologic fractures are common at the site of cysts. Aberrant calcification occurs with the increased mobilization of calcium from the bone. Renal stones are common. Dresser<sup>11</sup> emphasizes the importance of ruling out hyperparathyroidism in every case of bone rarefaction associated with renal calculus formation.

Diffuse bone rarefaction similar to that seen in hyperparathyroidism occurs in occasional cases of generalized xanthomatosis, metastatic malignant conditions, multiple myeloma and the malacias of nutritional origin but may be differentiated by the dissimilarity in skull changes. The granular appearance of the skull tables cannot be considered pathognomonic of primary hyperparathyroidism, however, since similar roentgen changes have been described in renal rickets<sup>12</sup> and

Fig. 6 (case 2)—A clubbing of the fingers in hyperparathyroidism due to decalcification of the terminal phalanges B with recalcification nine months after operation (C)

cion is first aroused by the finding of osteoporosis and osteitis fibrosa with cyst formation in the roentgenogram, often fortuitously. As described by Camp<sup>10</sup> and others, the outstanding feature of hyperparathyroidism is the generalized decalcification of the skeleton producing an osteoporosis of varying severity in different locations. In the skull the calvarium exhibits a finely granular appearance, the bones may become thickened and the tables indistinct. Small cysts may be present. In the long bones the decalcification leads to a marked thinning of both the cortex and the trabeculae, with indistinct, irregular and fuzzy outlines. Cyst formation may be present in the central portion of the shafts or subperiosteally. The vertebrae show a granular pattern much like the calvarium with an added coarsely striated appearance. The same applies to the pelvis where cysts are a common finding. When the disease is of long standing there is a marked loss of substance in the terminal phalanges, which are often almost completely resorbed (fig. 6). The remains of the tufts appear granular and there is a peculiar clubbing of the finger tips due to loss of the supporting

pituitary basophilism.<sup>13</sup> Histologic bone changes of the same character have been described in long-standing nephritis with and without parathyroid enlargement.<sup>14</sup> These may represent states of what has been called "secondary hyperparathyroidism." Case 7 of our series, which falls into this group, showed marked grainy mottling of the skull (fig. 7).

#### MINERAL METABOLISM IN HYPERPARATHYROIDISM

Most of the cases investigated show, or purport to show, a more marked negative calcium and phosphorus balance than normal on low intake of these elements. An intake greater than what is believed to be ordinarily adequate was usually required to maintain the patient in equilibrium. However, variations greater than those occurring in normal persons<sup>15</sup> might not be demonstrable in mildly progressive forms of the

disease or in remission. Cases of osteomalacia, hyperthyroidism, chronic steatorrhea, "fibrocystic disease," multiple myeloma and carcinoma with bone metastases may also be in negative calcium balance. An increased ratio of calcium in the urine to total calcium excretion is characteristic of hyperparathyroidism but may not be present if renal function is markedly impaired.<sup>16</sup> Elevation of the serum calcium above 11.5 mg per hundred cubic centimeters was reported in seventy-three of the seventy-eight cases in which determinations were recorded, in fifty-nine cases being consistently above 12 mg. In this series, therefore, about 25 per cent of the cases failed to show a consistent hypercalcemia. Some early cases, in evident negative calcium balance but with normal serum calcium, later presented hypercalcemia. Hypercalcemia is frequently found in multiple myeloma,<sup>16</sup> as in three cases recently seen (16.1, 15.7, 15.3 mg per hundred cubic centimeters), usually associated with hyperproteinemia. Hypercalcemia is occasionally observed in carcinoma with bone metastases,<sup>17</sup> as in three of our cases (13.4, 13.1, 12.3 mg per hundred cubic centimeters). The serum calcium was normal in all our cases of focal osteitis fibrosa, Paget's disease, and other diseases involving the bones.<sup>17a</sup> This is in agreement with most recent authors.<sup>18</sup> In osteomalacia and chronic steatorrhea, the serum calcium may be low. Consistent depression of the serum inorganic phosphorus below 2.5 mg per hundred cubic centimeters was found in only twenty-six of the fifty-two cases in which determinations were recorded. Low values are also observed in low phosphorus rickets and osteomalacia.

In chronic nephritis with severe renal insufficiency the serum inorganic phosphorus rises and the serum calcium tends to fall. For this reason, as pointed out by Albright and his associates,<sup>19</sup> the hypophosphatemia and hypercalcemia of uncomplicated primary hyperparathyroidism may not be present when there is an associated marked impairment of renal function. The normal or high serum inorganic phosphorus and the apparently normal serum calcium values observed in cases 2 and 4 and in some cases in the literature might be explained by associated renal insufficiency. In some instances, apparently normal serum calcium values were higher than expected, when derived by the empirical formula of Peters and Eiserson

$$\text{Ca} = -0.255 \text{ P} + 0.556 \text{ protein} + 7$$

That the significance of serum calcium values cannot be fully determined unless the serum inorganic phosphorus and protein content are known<sup>19</sup> holds with particular validity in hyperparathyroidism.

Increased blood phosphatase activity was reported in all of the fifteen cases of classic hyperparathyroidism investigated. Increased serum phosphatase activity within the range observed in hyperparathyroidism may be encountered in monostotic and polyostotic Paget's

disease, in mild and healing rickets and in osteomalacia of the low phosphorus type.<sup>20</sup> Very high values are obtained in active rickets (from 30 to 165 units<sup>21</sup>) and in generalized Paget's disease<sup>21</sup> (50-135 units<sup>21</sup>). Variable increases are observed in disturbed liver function, particularly in obstructive jaundice.<sup>22</sup> In our cases of focal osteitis fibrosa, multiple myeloma and "senile osteoporosis," the serum phosphatase values were normal,<sup>17a</sup> in agreement with most authors.<sup>23</sup> In our cases of carcinoma with osteoclastic metastases to the bones the serum phosphatase was either normal or somewhat increased, rarely over 12 Bodansky units. In three instances with liver metastases, without jaundice, and with normal serum calcium, the serum phosphatase was within the range found in hyperparathyroidism (25.1, 20.4, 20.1 Bodansky units).<sup>17a</sup> From the evidence now available, it would seem that a diagnosis of hyperparathyroidism is probably not indicated in cases presenting definite bone lesions, if the serum phosphatase activity is not definitely increased, particularly if the serum calcium is also normal. According to Albright and his

Fig. 7 (case 7)—Long standing renal insufficiency with skull changes identical with those in classic hyperparathyroidism.

associates<sup>17</sup> the phosphatase may not be elevated in very early cases without demonstrable pathologic changes of bone.

Clinical, roentgenologic and metabolic study usually suffice to distinguish hyperparathyroidism from bone rarefactions encountered in focal osteitis fibrosa, osteomalacia, multiple myeloma, neoplastic diseases of or metastases to the bones, Paget's disease, osteogenesis imperfecta, renal rickets, Hodgkin's disease, generalized xanthomatosis, basophilic adenoma, enchondromas, osteoporosis associated with chronic steatorrhea, senility, disuse or dietary deficiencies, "fibrocystic disease" and other syndromes less sharply defined. Occasionally, a biopsy is necessary. If thorough investigation yields indecisive or conflicting results, surgical exploration

for parathyroid tumor is indicated and should include aberrant sites<sup>24</sup> if no tumor is found in the usual areas.

Three recent atypical cases illustrate interesting problems in differential diagnosis.

**CASE 5**—H. W., a Jewish man, aged 37, is deformed and bedridden. His history was summarized up to 1929 by Dr. I. S. Hirsch.<sup>25</sup> Since the age of 6, his course has been one of progressive incapacitation due to numerous deformities, bone swellings and pathologic fractures with marked loss of weight and asthenia but comparatively little pain. The skeleton shows marked decalcification, with numerous cysts, and coarse granular mottling of the skull. Serum calcium has always been normal, serum inorganic phosphorus from 2.5 to 3.5 mg per hundred cubic centimeters, serum phosphatase from 22 to 28 Bodansky units. Renal function is unimpaired. Mineral balance studies (fig. 3) showed marked negative balance without increased calcium excretion in the urine. Biopsy of the bone was variously interpreted as "dysplasia" and osteitis fibrosa. Extensive exploration on two occasions failed to disclose a parathyroid tumor. High calcium diet, viosterol, intensive roentgen therapy to the neck and mediastinum have been without benefit. The diagnosis remains uncertain.

**CASE 6**—A. O., an American woman, aged 60, obese, has polyostotic Paget's disease complicated by repeated fractures of the right leg necessitating marked restriction of activity. In addition to typical Paget changes elsewhere, the pelvic bones, lumbar spine and right leg show marked decalcification of bone with coarse trabeculations but no cysts. The serum calcium and phosphorus have always been normal, serum phosphatase 82 Bodansky units, calcium and phosphorus balance within normal limits (fig. 3).

Case 6 resembles some of those reported as illustrating what some authors believe to be transition stages between Paget's disease and hyperparathyroidism. No evidence of hyperparathyroidism was obtained in our case.

Case 7, for which we are indebted to Dr. R. F. Loeb, is of particular interest with respect to the relationship between chronic renal insufficiency (resulting from congenital anomalies of the urinary tract or following acute nephritis) and bone changes, as in renal rickets and 'secondary hyperparathyroidism'.

**CASE 7**—M. B., an American girl who died at the age of 24, had had increasingly frequent episodes of edema of the face and ankles since the age of 11. There was a persistent albuminuria, the phenolsulphonphthalein excretion never exceeded 5 per cent. The blood urea nitrogen was rarely below 45 mg per hundred cubic centimeters and in the last two years, was usually above 70 mg with marked nephritic acidosis. In 1931 the serum calcium was 9.6 mg per hundred cubic centimeters, serum inorganic phosphorus 8.3 mg and serum protein 6.6. The blood pressure remained normal for years but gradually rose to 170 systolic, 110 diastolic. Retinal changes were absent. No skeletal deformities developed. Roentgen examination showed marked granular mottling of the skull as in hyperparathyroidism (fig. 7) and a rachitic irregularity in the calcification zones of both clavicles at the sternal junction. She died in uremia in 1932. Autopsy showed a chronic glomerulonephritis with extreme renal atrophy. No metastatic calcification or abnormalities of the ureters were observed. No parathyroid tumor was found in routine examination of the neck organs.

#### CONCLUSIONS

Hyperparathyroidism should be considered in the presence of obvious skeletal manifestations such as spontaneous fractures, bone swellings particularly of

the jaws, gross deformities, and unexplained persistent pain in the bones. Obscure cases with presenting symptoms of marked polydipsia and polyuria, recurring renal calculi or unexplained asthenia with wasting of the muscles occasionally prove to be parathyroid adenomas. In most such cases the diagnosis of hyperparathyroidism may be confirmed or excluded by consideration of the history and clinical manifestations, roentgen study of the bones, increased serum calcium and phosphatase activity, low serum inorganic phosphorus and mineral balance studies. The results of clinical or metabolic or roentgenologic investigation alone may be indecisive or misleading. This is particularly true in the presence of marked renal insufficiency, or when the disease is in its early stages, is only mildly progressive or is in remission.

### ACUTE ANTERIOR POLIOMYELITIS IN PHILADELPHIA

#### A COMPARATIVE STUDY OF THE 1916 AND 1932 EPIDEMICS

J. NORMAN HENRY, M.D.

Director, Department of Public Health

AND

GEORGE E. JOHNSON, M.D.

Chief and Diagnostician, Division of Communicable Diseases,  
Department of Public Health

PHILADELPHIA

The year 1932 witnessed the second extensive outbreak of epidemic poliomyelitis in Philadelphia, the first being in 1916. In the intervening years no definite outbreaks occurred although the years 1921, 1927 and 1929 to 1931 inclusive exhibited, as graphically represented in chart 1, an unusual number of cases. In the 1916 epidemic there were reported 1,006 cases and 307 deaths, a case death rate of 30.4 per cent. In the 1932 epidemic there were 728 cases and eighty-four deaths, a rate of 11.5 per cent. The respective death rates, however, are hardly comparable, since in 1916 the diagnostic criterion was paralysis whereas in 1932 many cases in the preparalytic stage were included. Not only was the fatality rate lower in the 1932 epidemic but the type of disease was less severe, resulting in relatively less permanent crippling.

#### SEASONAL AND GEOGRAPHIC DISTRIBUTION

The peak in both epidemics was reached in the fourth week of August with 133 and 118 cases, respectively. The greatest number of cases reported in a single day was thirty-six on August 22, 1916, and twenty-four on August 29, 1932.

The parallelism runs fairly true as to location of first appearance and geographic distribution. Both epidemics seem to have originated during the month of July from a focus in South Philadelphia. In 1916 there was a coexisting focus in North Philadelphia, and in 1932 a similar accessory focus in North-Central Philadelphia. In both years the disease extended to involve consecutively North and Northwest Philadelphia, and North and Southwest Philadelphia.

#### PREVALENCE IN ADJACENT LOCALITIES

The simultaneous prevalence of the disease in adjacent suburbs along the main line including Merion, Devon, Narbert and Haverford, and in the adjoining

<sup>24</sup> Mandl, Felix. Zur Technik der Parathyroidektomie bei Ostitis fibrosa auf Grund neuer Beobachtungen. Deutsche Ztschr. f. Chir. 240, 362, 1933. Churchill, E. D. and Cope, Oliver. Parathyroid Tumors Associated with Hyperparathyroidism. Surg. Gynec. & Obst. 58, 255 (Feb.) 1934.  
<sup>25</sup> Hirsch, I. S. Generalized Osteitis Fibrosa. Radiology 13, 44 (July) 1929.

city of Camden was noticeable early in August. Seashore resorts within the city's commuting area were similarly afflicted, and a goodly number of resident children ill with the disease were returned home, some with the source of infection traced here, others to the resorts proper. The department of public health constantly endeavored to keep in close touch with the surrounding suburban areas in order to anticipate any localized prevalence of the disease. Throughout the counties of the commonwealth not adjacent to Philadelphia County the prevalence was normal or only slightly above. In the adjoining counties, however, the increased prevalence was early recognized and for the year totaled seventy-one cases in Montgomery, eighty in Delaware, twenty-two in Chester and fifteen in Bucks County. Exclusive of Philadelphia County there were 422 cases and sixty-five deaths reported throughout the state in 1932. In none of the large cities of the country did the prevalence rate approach that of Philadelphia.

#### SERUM PREPARATIONS IN 1931

In 1931 the city of New York experienced its third epidemic and by the middle of July was reporting twenty-five cases daily. It was early realized that Philadelphia, because of its proximity and ease of accessibility, was in great danger of sharing in this epidemic. A list of persons who had recovered and contacts from the 1916 epidemic was compiled, and consents were obtained among those over 16 years of age for donation of blood. The laboratory of hygiene of the bureau of health prepared the serum and dispensed it in measured containers for free distribution to physicians and hospitals. About 10,000 cc of serum was so prepared but not all consumed, since the expected epidemic did not materialize.

#### BLOOD DONORS IN 1932

Early in June 1932 the department of public health, doubly apprehensive, formulated a working plan of attack and outlined an emergency program as well. Blood donors were again solicited and resolicited, so that approximately 38,000 cc of serum was pooled for distribution to city and out of town areas. Blood had been contributed voluntarily by 1,139 persons, in 314 instances from persons who had recovered. Of the remaining there were 529 cases of contact and 296 in which the donors were normal persons who had not come in contact with the disease. In the latter part of August, on account of the shortage of serum, it became necessary to appeal for additional donors through the county medical society's weekly roster, the press, the radio and the pulpit.

#### USE OF BLOOD FOR PROPHYLAXIS

The injection of whole blood or serum, preferably pooled, from recovered, contact or other normal adults for prophylactic purposes was urged by the department early in August. This procedure was followed in many of the general hospitals as well as in private practice. The following data have been collected from these hospitals and from our own case records:

In fourteen hospitals, 2,255 children were immunized, of this number all received parents' whole blood excepting 320, who received both whole blood and convalescent serum. The average dose of whole blood was 60 cc and of convalescent serum, 20 cc. One hospital immunized 1,341 children among whom three cases of anterior poliomyelitis developed. Our records show

twelve cases of the disease in immunized children, four of whom developed frank paralysis and the remainder a nonparalytic type.

A tabulation of the twelve cases with the interval in days, preparation used, cell count and clinical type of disease is given in table 1.

#### HOSPITALIZATION

In the beginning of the epidemic, for purposes of diagnosis, hospitalization and serum requirement, the city was divided into four districts, each in charge of a diagnostician. The Philadelphia General Hospital was opened for cases not otherwise cared for in general hospitals. Permission was given general hospitals to admit cases in cubicles or separate wards with facilities for sterilizing utensils, linens, and the like, and in charge of special nurses observing medical asepsis. Early in August, in order to secure additional beds and

Chart 1—Anterior poliomyelitis in Philadelphia 1910-1932 solid line, deaths broken line cases

treatment facilities for the increasing prevalence, the wards of the Philadelphia Hospital for Contagious Diseases were opened.

#### PHILADELPHIA HOSPITAL FOR CONTAGIOUS DISEASES

All cases reported were first examined by a representative of this department before hospitalized or quarantined at home. The nurses on the ambulance, in addition to securing a history of present illness and past diseases, instructed the parents to report at once at the hospital to donate blood for serum. Patients on admission were classified, so that those in the pre-paralytic stage or early paralytic stage were placed in an acute ward, and the late paralytic cases in a convalescent ward. Cases of doubtful diagnosis were isolated in cubicles until the diagnosis was determined. The latter group comprised those presumably in the abortive stage as well as those with other indetermined acute infections. Lumbar puncture was done in all cases on admission, and immune serum was adminis-

tered to all with clinical or laboratory evidence of poliomyelitis and to those in whom an active progressive infection was observed with or without evidence of paralysis. Serum was not given in afebrile cases exhibiting definite paralysis without progressive symptoms. A minimum of 100 cc of immune serum, 40 cc of convalescent serum and 60 cc of contact serum constituted the initial dose. Whole blood was at times substituted for part serum when the supply of the latter was low. Two Drinker respirators were in constant use, and when both were occupied respiratory cases were temporarily transferred to nearby hospitals similarly equipped. During the outbreak there were 410 cases admitted, of which 304 or 74 per cent, were diagnosed as epidemic poliomyelitis. The remainder, 106, or 26 per cent, were diagnosed as other acute infections, including probably some abortive cases of

As far as is known, not a single secondary case developed among other patients in any hospital admitting poliomyelitis cases. This has been a universal experience and tends to emphasize the feebly communicable character of the disease in its clinical phase. The excellent medical and nursing care received in hospitals contributed in no meager way to the conservation of life and freedom from serious after-crippling.

#### HOSPITAL DISCHARGES QUARANTINED AT HOME

Acute cases in all hospitals, physical condition permitting, were transferred to home addresses, if the premises were private after the temperature, pulse and respiration had remained normal for one week and there were no evidences of further extension of paralysis. They were transported in the Philadelphia Hospital for Contagious Disease ambulances, and home

the disease. Of those diagnosed as poliomyelitis, 152, or 50 per cent, showed evidences of weakness or paralysis on admission, and 192, or 63.2 per cent, showed the same symptoms on discharge, an increase of over 13 per cent.

There were twenty-four deaths at the hospital, a case death rate of 7.89 per cent, as compared with 13 per cent in 1916.

The general hospitals of the city were very cooperative and in many instances, with beds full, continued to make room for the newcomer. In 1932 there were 360 patients, or 50 per cent, admitted to general hospitals, of whom fifty-three died, a case fatality rate of 14.7 per cent. The total number of cases hospitalized was 664, or 91 per cent, with a fatality rate of 11.6 per cent. There were sixty-four or 8.89 per cent, of cases quarantined at home, with seven deaths, a case fatality rate of 10.9 per cent. In 1916, 76.7 per cent were hospitalized and 23.4 per cent treated at home, the fatality rate in hospitals was 22.6 per cent, and at home, 53.2 per cent.

premises were placarded for the remainder of the quarantine period of twenty-one days.

Discharged patients were given a list of instructions regarding further isolation and quarantine and were referred to the family physician for continued surveillance. Here again not a single secondary case developed in the homes of those so discharged. The Division of Child Hygiene was notified as a routine of all hospital discharges and sent its nurses to the homes for the purpose of instructing the heads of families in the rules of quarantine and of securing proper medical attention and supplies. This service was secured through the Emergency Aid, which organization had been instrumental in the rehabilitation of the 1916 group. This medical follow up, whether in home or hospital cases, was sufficiently comprehensive to include the prompt services of an orthopedic surgeon, the purchasing of needed braces and appliances, the transportation of convalescents to and from hospital clinics, and rehabilitation through occupational therapy with vocational guide and placement service. Cases discharged

with revised diagnoses were likewise visited by the nurses and observed by the medical inspectors for a period of fourteen days to detect evidences of muscular weakness or partial paralysis acquired in the interim.

#### COOPERATION OF THE MEDICAL PROFESSION

In the early days of August the director of public health, anticipating the gravity of the situation, called a joint meeting of the representatives of the county medical society and the health officers for the purpose of discussing ways and means of combating the disease. A plan was formulated for physicians familiar with the diagnosis of poliomyelitis to volunteer their services as diagnosticians to the department should an emergency arise. It was further suggested that general hospitals function as neighborhood centers for the examination of spinal fluids in suspected cases. In the latter part of the month neurologists and orthopedists in joint meeting proffered their services in the wards of the Philadelphia Hospital for Contagious Diseases, and in those of their own appointed hospitals for the treatment and after-care of the seriously crippled. This group functioned with great credit to all concerned. Reinforced by the cooperation of the county medical society, the medical profession at large, the hospitals, the civic organizations, the social workers and nurses, the public press, the radio and the pulpit, the health department was well entrenched to cope effectively with this epidemic.

#### DIAGNOSTIC AND CONTROL MEASURES

All suspicious and positive cases reported were seen for diagnosis and when doubtful the services of the district diagnostician were solicited. In all cases hospitalization was urged unless adequate home facilities prevailed. Cases of doubtful nature were likewise removed to a hospital for further clinical and laboratory study. The premises in home cases were placarded for the quarantine period of twenty-one days and the contacts kept under observation for fourteen

No serum	100	67	67.0	23	23.0	10	10.0

days. When patients were removed to a hospital, others in the same household were placed under observation quarantine and the premises placarded with an observation placard for the incubation period of two weeks. Contact food-handlers, school children, school teachers and others engaged in school work were excluded from employment during this period.

#### IMPORTED CASES

The importation of cases from the suburbs, outlying towns and nearby resorts by physicians and the public alike not only added to the increased prevalence and fatality rate but seriously interfered with the proper functioning of public health control. Many cases were conveyed to hospitals by physicians in their own cars, others in private conveyances to physicians' offices, and from there relayed to the Philadelphia General Hospital and the Philadelphia Hospital for Contagious Diseases

or to other hospitals, still others were boldly conveyed to the very gates of the contagious disease hospital.

During the 1932 epidemic there were forty-one cases of the disease admitted from out of town to the Philadelphia General Hospital and the Philadelphia Hospital for Contagious Diseases and to other hospitals in this irregular way. Of our own residents eighty-four contracted the disease out of the city, and 603 were supposedly infected at home.

#### BOARD OF HEALTH DEFERS OPENING OF SCHOOLS

August 31, by a resolution of the board of health, the opening of schools was postponed and assemblages of persons under 18 years were forbidden in public and

TABLE 4—One Hundred and Fifty-Two Preparalytic Cases on Admission to the Philadelphia Hospital for Contagious Diseases With and Without Serum

	Admitted Preparalytic	Discharged Nonparalytic	Paralyzed	Per Cent Paralyzed	Deaths	Per Cent

No serum	22	12	10	45.6	0	0.0

semipublic places. This was a precautionary measure well taken and met with the approval of educators and the public alike. The ban was completely lifted, October 5.

The epidemic of 1932 did not parallel that of 1916 in degree of prevalence, extent of virulence, or fatality rate. This may, in part, be attributed to the constant urge of early diagnosis and isolation, to the prompt reporting and hospitalization, to the early use of convalescent serum and to a possible neutralization of the virus itself.

#### END RESULTS OF A FOLLOW-UP SURVEY

A follow-up survey of 605 cases was made by medical inspectors in March 1933, including 407 cases with paralysis or muscular weakness and 198 without paralysis at the time of the original report. The end results in these cases were tabulated in accordance with the standards for measuring the degree of paralysis by the Harvard Infantile Paralysis Commission. While these end result examinations were not checked against similar examinations made at the time of the original report, they nevertheless serve as fairly accurate estimates of degree of recovery in the groups specified.

Table 2 represents these results with a further division into those treated with and without serum. There are 119 other cases in which no follow up was possible, as well as the total deaths tabulated with regard to paralysis and no paralysis, with and without serum.

Of the total 605 cases investigated, it is interesting to note that 265, or 43.8 per cent, are classified as normal or completely recovered, and that of these 128, or 48.3 per cent, originally showed weakness or paralysis, and 137, or 51.7 per cent, did not. There are 248 cases, or 41 per cent, showing varying degrees of residual paralysis, and twelve patients are totally paralyzed. Of the patients 407, or 67.3 per cent, received serum, 179, or 44 per cent, of whom recovered, and 198, or 32.7 per cent, did not receive serum, of whom eighty-six, or 43.4 per cent, recovered. Of the 304 cases admitted to the Philadelphia Hospital for Contagious Diseases, 192, or 63.5 per cent, showed evi-

dences of weakness or paralysis, and 112, or 36.5 per cent, did not.

Regarding serum treatment, 254, or 83.5 per cent, received serum, and fifty, or 16.5 per cent, did not. Of the 254 receiving serum, 124 presented evidences of weakness or paralysis on admission and 130 did not, of the fifty who did not receive serum twenty-five showed evidences, and twenty-two did not. Among twenty-four deaths at this hospital, eighteen, or 75 per cent, of the patients had serum, and six, or 25 per cent, did not.

#### TREATMENT WITH AND WITHOUT SERUM

Tables 3 and 4 represent the end results in 198 preparalytic cases and the results on discharge of 152 preparalytic cases at the Philadelphia Hospital for Contagious Diseases in which treatment with and without serum was given.

The normal end results obtained in 265 cases previously tabulated, of which 179, or 67 per cent, were

Chart 2—Comparative monthly incidence of cases and deaths from anterior poliomyelitis in Philadelphia 1916-1932. White rectangles cases, black rectangles deaths.

serum treated, are favorable to its use, but unfortunately the cases were not divided into comparable groups numerically or by case classification. Regarding the end results in 198 preparalytic cases, 98 with and 100 without serum, the serum group shows an advantage. In the 152 preparalytic cases at the Philadelphia Hospital for Contagious Diseases the paralysis percentage is proportionally less in the serum treated, but the death percentage is higher, probably because there were more cases of the severer grades of paralysis included. It is generally conceded that immune serum is of no value after the onset of paralysis, yet its use was not limited to the preparalytic type either in home cases because of insistence of parents or in hospital cases showing febrile and progressive symptoms.

The small number of preparalytic cases with controls shows no decided advantage in favor of the serum treated group. While there is no conclusive evidence

presented in favor of the use of serum, we feel that for want of a specific therapeutic agent its use should be continued in the early preparalytic cases, checked whenever possible by comparable controls until a final evaluation is determined on. A comparative estimation of the routes of administration of serum shows that the intravenous was used in 37 per cent of cases, the intramuscular in 56 per cent, and spinal in combination in 2.5 per cent. Whole blood was used in combination in 22.5 per cent and transfusion in 2 per cent. There were 1,062 spinal counts made by the Division of Laboratories, 754 of which showed a count of over 12 per cubic millimeter. The average cell count for all cases was 88 per cubic millimeter and the highest count was 1,500 per cubic millimeter.

#### CROSS PROTECTION

In an effort to determine what bearing cross protection in infections may have on immunity to poliomyelitis, a careful history of previous acute infectious diseases taken in all cases admitted to the Philadelphia Hospital for Contagious Diseases showed that 64.1 per cent of cases gave such a history with apparently no acquired protection as a result. Of the 304 patients, 56.3 per cent were vaccinated against smallpox, and 51.3 per cent had had diphtheria toxin-antitoxin. Enlarged tonsils, probably diseased, were present in 81.6 per cent of cases, presumptive evidence of a diseased nasopharynx with a consequent lowering of the virucidal property present in its normal secretions as determined by Amos and Taylor. A history of recent tonsillectomies was not compiled.

#### COMPARATIVE EPIDEMIOLOGIC DATA

The following data represent the most important epidemiologic features in an analysis of 728 case histories.

**Seasonal Incidence.**—The distribution of cases by months in chart 2 shows the seasonal variation. In both 1932 and 1916 the maximum prevalence occurred, in the order given, in the months of August, September and October. The onset in 1932 started later in July, but in both epidemic years the greatest monthly prevalence was in August, with the maximum number of cases reported in the fourth week. This high rate of prevalence was coincident with a high mean temperature and a low mean rainfall. The mortality curve follows that of the incidence with the greatest number of deaths in August and September of both years.

**Cases and Deaths by Sex and Age.**—Males were more susceptible than females in the proportion of 58.5 per cent to 41.5 per cent for 1932, and of 54.4 per cent to 45.6 per cent in 1916. The case mortality for males was slightly higher in 1932. In both epidemic years the age group 1 to 5 years prevailed, followed by the 5 to 10 year group. In 1916 no cases of patients over 30 years of age were reported. In the 1932 epidemic comparatively more cases occurred in the older age groups 5 to 10, 10 to 15, 15 to 20 years. The mortality rate was highest in the 1 to 5 year group in both years but in 1932 the rate was comparatively higher in the 5 to 10 and the 10 to 15 year groups.

Chart 3 represents the comparative percentage groups of cases and deaths in both epidemics.

**Color Grouping Cases and Deaths.**—In 1916 there were twenty-eight Negro cases as contrasted with 107 in 1932. This is attributed to an increase of 160 per cent in the Negro population since the 1910 census,

1 e, an increase from 84,459 to 219,599. The ratio of cases to deaths in both years is about the same for the Negro and the white race. In 1932 a similar trend toward the older age groups is observed.

**Multiple Cases in Families**—The infectiousness of poliomyelitis has frequently been questioned because of

**Relative Frequency of Symptoms and Signs**—The classic symptoms of fever, headache and vomiting, and the signs of hyperesthesia, irritability, twitchings, tremors, stiffness of the neck and rigidity of the spine are prominently represented in table 6.

It is interesting to note that the average number of days between the onset of illness and the visit of the physician was three days, between the physician's visit and the date of report three days, and from the date of onset to the appearance of paralysis three days.

**Distribution of Paralysis of Extremities**—The right leg was found to be the most frequent single extremity involved, followed by the left leg and then both legs. The right arm was more frequently involved than the left, as table 7 shows.

\* Initial case

**Clinical Types of Paralysis**—As usual, the spinal type of the disease predominated and was represented in 62.37 per cent of the 497 cases presenting weakness or paralysis.

There were 107 cases showing muscular weakness and 231 preparalytic cases presenting the clinical symptoms and spinal fluid changes of this type.

Chart 3—Cases and deaths acute anterior poliomyelitis comparative age groups in percentage 1916 and 1932

the large number of families with children in which only one case occurred. In 1932 there were twenty-five family groups in which more than one case developed, as contrasted with fourteen similar groups in 1916. There were twenty-four families with two cases, and one family with three cases.

In these multiple-case groupings it is important to distinguish between those that may be regarded as true secondary cases and those in which infection resulted from a common or independent source. Among our so-called secondary cases there are three abortive, thirteen preparalytic and ten paralytic cases. According to Aycock and Eaton, the subsequent cases occurring in families up to an interval of eight days are probably of common source infection, and those from the ninth to the seventeenth day, averaging fourteen, are probably true secondary cases. In our series there are apparently six true secondary cases: two at nine, two at ten, one at eleven and one at nineteen day intervals. One case that occurred after an interval of twenty-four days is probably of a common or independent source of infection. These authors conclude by saying that in poliomyelitis the recognized case of the disease is relatively a far less important cause of infection than in scarlet fever or diphtheria, and that in poliomyelitis it is not so much the case itself as the source from which the case was infected.

Table 5 gives the interval in days between primary and subsequent cases.

SUMMARY

The 1932 epidemic differed little in its seasonal incidence or geographic distribution but much in its morbidity and mortality rates from the 1916 epidemic. There were a total of 728 cases and 84 deaths reported in the former and 1,006 cases and 307 deaths in the latter year. The case death rate in 1932 was 11.5 per cent, or 56 per hundred thousand of population, in

TABLE 6—Relative Frequency of Symptoms and Signs in Percentage

Symptom	Per Cent	Symptom	Per Cent
Fever	92.5	Convulsions	3.8
Headache	66.2	Chills	14.7
Vomiting	48.0	Coryza	2.2
Pains	37.1	Stiffness of the neck	50.4
Irritability	33.2	Rigidity of the spine	24.0
Drowsiness	19.9	Kernig sign	6.7
Hypersensitivity	2.2	Babinsky sign	3.0
Constipation	16.0	Muscular twitching	6.7
Diarrhea	14.7	Tremors	3.4

1916 30.4 per cent, or 18 per hundred thousand of population. There were many more cases diagnosed and reported in the preparalytic stage during the recent outbreak, resulting in a greater number of recovered cases. In addition to a proportionally greater number of recovered cases there was a substantial reduction in the paralyzes of the more severe grades, as evidenced in the end results of the follow up group of 605 cases, among which 43.8 per cent were classified as normal,

TABLE 7—Relative Frequency of Paralysis of Extremities in Percentage

Part	Per Cent	Part	Per Cent
Right leg	8.3	Left arm	4.6
Left leg	7.9	Both arms	1.6
Both legs	7.3	Both arms and both legs	1.6
Right arm	6.0		

14.4 per cent as good, 13.9 per cent as fair, 9.3 per cent as poor, 3.4 per cent as showing a trace of paralysis, 2 per cent as totally paralyzed, and 13.2 per cent as deaths.

Early diagnosis and isolation, prompt reporting and hospitalization, serum therapy and appropriate after-care were consistently urged on the profession.

The susceptible age group in both epidemics was the 5 to 10 year group, with the higher age groups involved to a greater degree in the 1932 outbreak. In the latter,

TABLE 8—Types of Paralysis

Paralysis	Number of Cases
Spinal	310
Bulbospontine	70
Landry's	6
Cerebral	3
Polio-encephalomyelitis	1

57 per cent of the cases and 45 per cent of the deaths were in the age group under 5 years, whereas in 1916 88 per cent of the cases and 85.4 per cent of the deaths were so differentiated. The greatest seasonal incidence encompassed the summer months, coincident with the high temperature and low rain fall.

No conclusive evidence is offered with regard to the value of passive immunization by the use of whole blood or serum.

The use of human immune serum for treatment in the early preparalytic cases seems justified by the end

results obtained in a small series of cases and controls. The dearth of true secondary cases in families, hospitals and institutions serves to emphasize the fact that infection by direct contact with clinical cases is not common. Human carriers apparently constitute the reservoir for the virus.

The closing of schools and swimming pools and the restricted attendance at the moving picture theaters certainly prevented mass contact exposure, but at no time were they considered as foci of infection.

No epidemic can be successfully checked and the damage repaired without the whole-hearted cooperation of the medical profession, the hospitals, the public and the various coordinating agencies, including the nurses, the social service workers, the public press, the pulpit, the radio and, finally, such organizations as the Emergency Aid, whose interest in the after-care and treatment of those left crippled completes the list.

City Hall Square

THE ABSENCE OF DETERIORATING EFFECTS OF BROMIDES IN EPILEPSY

HARRY A. PASKIND, M.D.  
CHICAGO

Bromine was discovered by Balard<sup>1</sup> in 1828, he was also the first to produce potassium bromide. In 1850 Huet<sup>2</sup> published a study of the action of potassium bromide and stated that it causes general and sexual sedation, anesthesia of the palate and throat, mental torpor, disorders of motility and cutaneous anesthesia.

Locock<sup>3</sup> first used bromides in epilepsy and noted its favorable effect. Later Voisin<sup>4</sup> and Brown-Sequard<sup>5</sup> systematized and made clear the use of bromides in this disorder, and ever since they have been in general use. That they diminish the number and severity of seizures has been demonstrated times beyond number.

The reputation of bromides is, however, not unsullied, for many writers, old and modern, have stated that in patients with epilepsy they produce mental deterioration.

Eccheverria<sup>6</sup> in 1870 stated that a single dose of from 10 to 20 grains (0.65 to 1.30 Gm.) had caused patients with epilepsy to become maniacal, suicidal, hallucinatory and melancholic. Bannister<sup>7</sup> described an orderly patient with epilepsy who on 15 grains (1 Gm.) of bromide three times daily became a "dangerous lunatic," the imputation being that bromide caused the mental change. Jewell<sup>8</sup> believed that many persons with epilepsy were in asylums not because they had epilepsy but because they were treated with bromides. Bennett<sup>9</sup> wrote that, in 18.8 per cent of epileptic patients treated with bromides, mental weakness developed. Hare<sup>10</sup> stated that mental changes in epileptic

patients are greatly increased by the constant administration of bromides, Huchard<sup>8</sup> wrote that they affect the intelligence, Collins<sup>9</sup> that, in epileptic patients, bromides produce "colossal" mental and physical depravity, and Maguire<sup>10</sup> expressed the opinion that the prolonged administration of bromides is liable to produce changes in the cortical nerve cells, such as chromatolysis and complete dissolution with consequent dementia, but he did not adduce histologic evidence. Weir Mitchell<sup>11</sup> stated that effective doses of bromide may produce loss of memory, inertness, low spirits and, in rare cases, forms of melancholia, maniacal excitement and even suicidal or homicidal mania. Davy<sup>12</sup> believed that the continued use of bromides in patients with epilepsy produced physical and mental enfeeblement, and Rayner<sup>13</sup> that the use of bromides was in many instances responsible for the institutionalization of previously sane persons with epilepsy. Hunt<sup>14</sup> states that the prolonged administration of bromides may cause a condition akin to dementia paralytica. Sollmann<sup>15</sup> states that long continued use of bromides leads to psychic deterioration, which may disappear when the drug is stopped or reduced. Church<sup>16</sup> wrote that it was a frequent experience to see patients with epilepsy "brutalized" by bromides go months without fits but with a loss of mental and physical activity. Clark<sup>17</sup> advised that the use of bromides be discontinued in epilepsy because they produce symptoms just as bad as the disease itself. Wechsler,<sup>18</sup> in a recent textbook, says "It is said that bromism may cause mental deterioration." Muskens<sup>19</sup> stated that there is no doubt that most cases of epilepsy in which bromides have been used over a period of years do present very serious mental deterioration. Strecker and Ebaugh<sup>20</sup> wrote that bromides in large doses brutalize the patient with epilepsy.

These statements constitute a serious indictment against the use of bromides in epilepsy and, if true, would practically contraindicate their use.

I shall try to show that this impeachment of the use of bromides in epilepsy is unjustifiable. Such a demonstration I believe to be urgently needed, for a great many physicians, because of such authoritative statements, doubtless bolstered up by experience with the abuse of bromides, have come to use them timidly, half-heartedly, ineffectually or not at all.

The material used in this study consists of the records of fifty-four patients with epilepsy, from the private practice of Dr. Hugh T. Patrick, who have been treated with bromides for a year or longer. Of these, five were treated for one year, nine, two years, five, three years, three, four years, seven, five years, five, six years, four,

seven years, three, eight years, one, nine years, one, ten years, three, eleven years, two, twelve years, three, thirteen years, two, sixteen years, and one for seventeen years. Of these patients, three, or 5.5 per cent, were found to be mentally deteriorated. The remainder, or 94.5 per cent, showed not the slightest signs of deterioration or behavior disorder and performed their customary tasks, sometimes very responsible tasks, with the same efficiency as persons in good mental health.

In a previous study of 304 epileptic patients from the private practice of Dr. Patrick who had had the disease six years or longer, I<sup>21</sup> found that 6.5 per cent had deteriorated. In this group there were many patients who had received no treatment for years, or inadequate treatment, or periodic treatment, some had received adequate treatment throughout the course of the illness, in some the disease was not recognized as epilepsy until some months or years after the onset. It would seem then, that the occurrence of deterioration in the present group that received bromide medication continuously for a year or more is no greater than in the larger group in which treatment was in a few cases adequate but in most cases inadequate, periodic or absent and in which various remedies had been used including bromides (5.5 per cent deteriorated to 6.5 per cent, respectively).

In order to elucidate the question more clearly I have prepared the accompanying table, outlining the salient features of the cases dealt with in this report. A study of this table shows that the dosage of bromide employed was not inconsiderable, in almost all instances it was large enough to exert a favorable influence on the disease. In some cases the seizures disappeared while the patient was taking bromides. It may also be noted that regardless of how long the patient took bromides (with the exception of the three deteriorated patients) there was no educational or vocational decline.

Based on these observations I have come to believe that bromides in rather full therapeutic doses do not cause deterioration in patients with epilepsy and that statements in the literature regarding this point are in need of revision.

It remains to be explained why so many authors have believed that bromides cause deterioration in patients with epilepsy. The reasons for this are not far to seek.

I believe that one of the reasons that bromides are in such bad repute is the failure to adjust the dosage. A dosage that will produce salutary effects in one patient may produce signs of bromism in another. The symptoms of bromism have been well described by Turner<sup>22</sup> as follows:

This condition is characterized by a blunting of the intellectual faculties, impairment of memory and production of a dull and apathetic state. The speech is slow, the tongue tremulous, saliva may flow from the mouth, the gait is staggering and the movements of the limbs feeble and infirm. The mucous membranes suffer so that the palatal sensibility may be abolished and nausea, flatulence and diarrhea supervene. The action of the heart is slow and feeble, the respiration shallow and imperfect and the extremities blue and cold. Acne usually covers the skin of the face and back.

It must be remembered, however, that these symptoms of bromism are produced only by doses in excess of the patient's tolerance and that this is intoxication.

52	♀	31	16	Petit mal 1 2 per week Grand mal 3 8 per month	72 gr daily for 16 years	Reduced in frequency	Housekeeper	Housekeeper	None
53	♀	26	22	Petit mal 1 per month to 3 per week Grand mal 1 per month to 3 per week	66 72 gr daily for 16 years	Reduced in frequency	None	None	Deteriorated
54	♂	22	23	Petit mal 3 10 per day	66 gr daily for 17 years	Reduced in frequency	Lawyer	Lawyer	None

and not deterioration. That in many instances this intoxication has been mistaken for deterioration seems reasonable, and the observers of this intoxication have warned others against the use of bromides. But this intoxication disappears in a short time with proper reduction of the dose, while deterioration is chronic and ineradicable. This intoxication is no more deterioration than is a single episode of pronounced alcoholism.

Another reason for the undeserved bad reputation of bromides, I believe, is that bromides were given to patients who became deteriorated because of their epilepsy or its underlying cause. Some persons with epilepsy undergo mental deterioration, others do not. In a previous study of patients with epilepsy I<sup>21</sup> attempted to show that the occurrence of deterioration is correlated with certain factors in the patient's background and symptoms. The nondeteriorated patients come of a stock less heavily burdened with neuropathy than do the deteriorated ones, the onset in the nondeteriorated patients is later, they have attacks less frequently and they have more and longer remissions. It is these factors, I believe, that play a rôle in the occurrence of deterioration, and not the administration of bromides.

Finally, the reputation of bromides has undoubtedly suffered through their use in institutions for epileptic and mentally ill patients. Epileptic patients are sent to institutions because they are deteriorated or because they show behavior disturbances. Some days such patients are orderly, other days they are irritable, bad tempered, ugly, combative and even brutal. If bromides happened to be administered before or during such a period the bromides were held responsible, and toesins were sounded against their use. Here, again, a sequence in time was mistaken for cause and effect. Furthermore, the use of bromides had few defenders, because practically all men who wrote on epilepsy were institution men whose judgment of the value of bromides was colored by observations, such as those quoted, and who did not know that there are large numbers of persons with epilepsy who do not undergo mental changes and who are never institutionalized. On the extramural nondeteriorated patients they were unable to make sufficient observations regarding the effects of bromides.

#### CONCLUSIONS

Almost all writers on the use of bromides in epilepsy have stated that, although they are efficient in eradicating or ameliorating the seizures, they are dangerous in that they sometimes produce mental deterioration.

A study of fifty-four patients with epilepsy who have taken bromides in sufficient amounts to affect the seizures for from one to seventeen years show that only three, or 5.5 per cent, became deteriorated. The occurrence of deterioration in this more adequately treated group was less than in a larger, less adequately treated group.

The misleading statements in the literature regarding the adverse effects of bromide in epilepsy are due to (1) failure to distinguish between intoxication and deterioration, (2) the use of bromides in persons with epilepsy who were destined to deteriorate without their use, and (3) the chance occurrence of behavior disturbances in insane or neurotic epileptic patients who had received bromides and in whom such behavior disorders occur without bromides.

## ANTERIOR PITUITARY-LIKE PRINCIPLE IN THE TREATMENT OF MALDESCENT OF THE TESTICLE

SAMUEL COHN, M.D.

SAN FRANCISCO

In 1932, Engle<sup>1</sup> described the experimental production of descent of the testicle in immature monkeys by the injection of hormones of the anterior pituitary gland or substances obtained from pregnancy urine. Since maldescent of the testicle is a condition for which the physician is not infrequently consulted, it was felt that this observation might open up a new approach to the study and treatment of this developmental defect.

#### INCIDENCE

The incidence<sup>2</sup> of undescended testicle in army recruits is reported as varying from two to five per thousand applicants. Maldescent apparently occurs more frequently on the right side, since the descent of the left testicle normally precedes that of the right. The condition of maldescent is bilateral in about 25 per cent of the cases.

#### SURGICAL TREATMENT

Bevan<sup>3</sup> advises that an operation for undescended testicle be performed in the first or second year of life. He does not believe that the testicle ever spontaneously descends between birth and puberty if the organ cannot be manually forced into the scrotum.

Cabot<sup>4</sup> recommended that the operation for undescended testicle be performed before the age of 9 years and feels that the earlier it is done the better the result will be.

Others<sup>5</sup> concur with the exponents of surgery at an early age. Higgins<sup>6</sup> is of the opinion that operation is always indicated when the testicle cannot be palpated.

However, the results of surgical treatment are not sufficiently encouraging to warrant the degree of assurance with which these authors have stated their opinions. Goetsch<sup>2</sup> reports a follow up of fifteen operations for maldescent and found that the operated testicle had developed normally in only one case. Burdick and Coley<sup>6</sup> in a report on 537 orchidopexies were of the opinion that 50 per cent of the operations proved satisfactory as to position of the testicle and that in about 15 per cent of the cases the testicle was normal in size. Turner<sup>7</sup> reports the testis to be well down after operation in 70 per cent of the cases, and Pasten<sup>7</sup> reports thirty-one operations with good results in 32 per cent.

The newer Torek operation seems to offer a possibility of better end results when used by competent surgeons who have made a thorough study of the technic. Harris<sup>8</sup> has obtained good results in 100 per cent of his series of thirty Torek operations.

7 Cited by Higgins and Welti.<sup>6</sup>

8 Harris, F. I. Results of Thirty Torek Operations. to be published.

Drake<sup>9</sup> observed maldescent of the testicle in a group of school boys over a long period of time and is of the opinion that practically all these cases will show spontaneous descent. He believes that surgery has been utilized too freely in the past. Harris<sup>8</sup> reported that in his series of Torek operations performed in the majority of cases on subjects past puberty the testes were usually found to be small. He advises that when operation is indicated it should be done at or after puberty.

#### HORMONE TREATMENT

Lower and Johnston,<sup>10</sup> working with normal adult rats, found that injection of the gonad-stimulating hormone of the anterior pituitary gland resulted in stimulation of the testes as well as of the prostate and seminal vesicles. Evans, Meyer and Simpson,<sup>11</sup> also working with rats, injected anterior pituitary-like principles. These authors state that "though the testes did not appreciably increase in weight, the accessory organs increased markedly under the influence of gonad-stimulating hormone, attaining the size characteristic of these organs in young adults." Evans<sup>12</sup> repeated the foregoing experiments but stated in addition that the testicles themselves actually decreased in weight and seemed to be damaged by the treatment. Butcher,<sup>13</sup> using anterior pituitary-like substance, also in immature male rats, found that it accelerated spermatogenesis and increased the size of the testis. Brosius and Schaffer<sup>14</sup> noted the repeated production of spermatogenesis following the administration of anterior pituitary-like principle in a patient with complete aspermia with bilateral testicular atrophy following orchitis. Aspermia reappeared after withdrawal of the treatment. Engle's<sup>1</sup> work with monkeys, which forms the stimulus for this paper, has already been mentioned.

Goldman and Stern<sup>15</sup> reported the use of anterior pituitary-like principle in two human subjects for treatment of maldescent of the testis. The first patient showed coexistent evidences of glandular hypofunction. The conclusions regarding the second patient, aged 15, are open to criticism because of the possibility that spontaneous improvement may occur at this age, as noted by Drake<sup>9</sup>. However, both patients seemed to have been benefited by the therapy.

#### COMMENT

Although Evans<sup>12</sup> has stated that anterior pituitary-like principle may damage the testicle of the immature male rat, it would seem from the other instances mentioned that such a reaction does not occur in the human being. To the contrary, certain beneficial effects seem to result, such as an increase in the size and weight of the accessory sex organs (the seminal vesicles and the prostate) and an apparent increase in the length, weight and diameter of the spermatic cord. Furthermore, testicular function is apparently restored or augmented by injection of this substance.

#### METHOD

Since anterior pituitary-like principle had not been used in treatment of maldescent of the testicle in the human subject when the work which forms the basis of this report was started in February 1933, an arbitrary dosage was chosen. One cubic centimeter of the commercial preparation<sup>16</sup> containing 100 rat units was administered subcutaneously three times weekly until ten injections had been given.

#### REPORT OF CASES

CASE 1—A boy, aged 8 years, was normal in appearance and development, save for the fact that the testicles had never been noted in the scrotum. On examination the testicles were found to be located in the middle of the inguinal canal and could not be forced down past the external ring. Both testicles descended well into the scrotum after the second injection of anterior pituitary-like principle and were still there after six months.

CASE 2<sup>17</sup>—A boy, aged 9 years, of generally normal appearance as to size and development, showed maldescent of the right testicle. It was at the level of the internal ring and was movable only for a short distance. The testicle descended well into the scrotum after the second injection of anterior pituitary-like principle and remained there after six months.

CASE 3—A boy, aged 11 years, of generally normal appearance as to size and development, showed maldescent of the right testicle, which was at the midportion of the inguinal canal. It was manually reducible to the external ring. It descended six hours after the first injection of anterior pituitary-like principle and remained well down after four months.

CASE 4—A boy, aged 7 years, showed a slight tendency toward obesity and feminine conformation. The left testicle was well down in the scrotum and apparently was normal. The right testicle was not palpable. It became palpable at the level of the internal ring after the fourth injection. It did not descend farther. This child will probably require an operation.

CASE 5—A boy, aged 10 years, showed a definite Frohlich syndrome. A Torek operation had been done on the right side and the testicle had been found to be markedly atrophic. The left testicle was not palpable. After eight injections of anterior pituitary-like principle it became palpable in the scrotum. Twenty injections were given and the testicle rapidly became normal in size and position. After maintaining a normal position for about six months it began to rise into the canal. Six additional injections of anterior pituitary-like principle were given with a resultant descent of the testicle well down in the scrotum. The right testicle in the meanwhile had attained a normal size and position. The child's general condition improved greatly. The obesity seemed to be redistributed in a more normal manner, the genitalia became less infantile, and a growth of fuzz appeared on the cheeks.

CASE 6—A boy aged 12 years, had had a Bevan operation for bilateral testicular maldescent several years previously, with complete failure on both sides. A Torek operation was done on the right side and while he was convalescing, the patient was given a course of injections of anterior pituitary-like principle. The result was entirely satisfactory. The testicle remained well down in the scrotum. Pubic hair and fuzzy hair on the upper lip appeared shortly thereafter.

#### CONCLUSIONS

The anterior pituitary-like principle of pregnancy urine is apparently effective in causing the descent of undescended testicles when there is no anatomic malformation to act as a mechanical obstruction. When an obstruction exists, a partial descent will occur, but operation will be required to complete the process. In surgical cases, anterior pituitary-like principle is a valuable adjunct in the production of a successful outcome.

## SUMMARY

Four otherwise normal children were treated for maldevelopment of the testicle with subcutaneous injections of anterior pituitary-like principle. Three cases evidenced complete improvement. The fourth case showed evidence of mechanical obstruction and will require operation.

A fifth case presented one operated side, which furnished an admirable opportunity for a controlled observation and showed evidences of pituitary hypofunction. Both the condition of the testicles and the general glandular hypofunction improved under the therapy.

The sixth patient was operated on again after several years and injections of anterior pituitary-like principle were used as an adjunct to surgery. The result was entirely successful as to both the condition of the testes and the general condition of the patient.

## THE INHERITANCE OF DIABETES

PRISCILLA WHITE, M.D.  
ELLIOTT P. JOSLIN, M.D.  
AND  
GREGORY PINCUS, D.Sc.  
BOSTON

Is it possible to predict the onset of diabetes in a given individual at a given time? This question was uppermost in our minds, Dec. 17, 1931, for while we were treating a 5 year old girl for diabetic coma her solicitous similar twin sister waited nearby. Surely, we thought, if the theory of the inheritance of diabetes is correct here is an instance in which the prediction is possible. Our patient had just developed diabetes and the second twin should develop the disease and likely within a decade. April 10, 1934, the first child returned to the clinic with her twin sister. Three weeks previous to this the second twin had developed the symptoms of diabetes and her mother had found a red reduction with the Benedict test. At the clinic the diagnosis was confirmed, for the urine was found to contain 4.6 per cent of sugar and the blood 0.28 per cent.

The conception of the inheritance of diabetes is not new, for it was first described by Morton<sup>1</sup> in 1696 and has been emphasized by many students of the disease.<sup>2</sup> Inconsistencies in the series of reports are bound

to arise, first, because of the short duration of the life of diabetic patients prior to the use of insulin, so that the data of family histories have been incomplete and the mode of transmission has not been demonstrable, and, second, because some schools believe in the manifold origin and character of the disease and others in its unity.<sup>3</sup> The former may thus select for analysis only those patients who have a positive history of inheritance, and the latter will analyze consecutive case histories. We ourselves believe in the unity of the disease—unity of symptoms, manifestations, complications and the underlying cause. On this conception of the unity of diabetes our own analyses have been made.

The evidence of the inheritance of diabetes rests primarily on three facts: (1) the concurrence of diabetes in homologous twins, (2) the greater incidence of diabetes in the relatives of a diabetic person than in a control population, and (3), indirectly, on the demonstration that mendelian ratios are found in large series of case histories selected at random and in smaller series of families tested for accuracy of diagnosis and for latency of the disease.

The concurrence of diabetes in twins has already been described in the literature.<sup>4</sup> This has obviously suggested the inheritance of the disease, since in 80 per cent of the cases reported the twins were of the homologous type. No analysis of dissimilar twins has been made, but from such a comparative analysis much can be learned, for, if the disease is inherited, the incidence of diabetes in both similar twins should obviously exceed the incidence in dissimilar twins. The latter, in fact, all conditions being equal, should show the same inheritance as that found among ordinary brothers and sisters.

An analysis of our own data shows that forty-one of our diabetic patients have a twin. Of this group thirteen pairs were known to be similar and thirteen dissimilar. We were compelled to exclude fifteen sets of twins because of the death of one of the twins in infancy. Among nine of the thirteen sets of similar twins both were diabetic, whereas in only two of the thirteen pairs of dissimilar twins were both diabetic. The incidence among the siblings of control, diabetic and twins populations is compared in table 2.

It is evident that an overwhelming excess occurred among the group of similar twins.

The age incidence of diabetes must be considered here, for perhaps the excess in the similar twin group could be explained on the basis of greater age. This is not the case, for although 45 per cent of the individuals in the similar twin group were in the age incidence zone of 50 years, 35 per cent of the dissimilar twins were of the same age, and the median age of the two groups was in the same decade. The family history of diabetes in the two groups of twins was nearly identical, since there were three instances of parental diabetes among the dissimilar twins and two among the similar twins.

The statistically significant difference between the occurrence of diabetes in a diabetic and a control population<sup>5</sup> was that 2 per cent of the parents of our control population had diabetes whereas 8 per cent of the parents of our diabetic patients had the disease. Diabetes occurred ten times more frequently in the brothers and sisters of diabetic patients than in the control group.

Criticism of such data is often given that perhaps we selected unfairly against diabetes. This is not actually the case and is substantiated by the control series of German<sup>6</sup> and English<sup>7</sup> investigators.

Expected mendelian ratios of the simple recessive type were found in our three types of crosses (diabetic  $\times$  diabetic, diabetic  $\times$  carrier, carrier  $\times$  carrier). Among 800 odd consecutive families studied, ninety-eight diabetic patients (or 4 per cent) were found in the 2,309 siblings of the carrier  $\times$  carrier cross, forty-eight (or 10 per cent) in the 475 siblings of the diabetic  $\times$  carrier cross, and eight diabetic children (24 per cent) in the thirty-three instances of the diabetic  $\times$  diabetic cross. If our data had been complete we would have expected more<sup>8</sup>—16 per cent in the first, 40 per cent in the second and 100 per cent in the third—but this could occur only if all members of the families had attained old age. The significant fact is this. The expected ratios were 1 to 25 to 61, and the actual ratios were 1 to 24 to 57.

It is on this point and the concurrence of diabetes in homologous twins that the validity both of the initial hypothesis of inheritance and of the mendelian type of transmission rests, for if the basic etiology of diabetes were due to an infection, trauma or nutritional state it is highly improbable that such an excess would occur in homologous twins and less than one chance in a million that the three ratios would be fulfilled in this manner. Actually we have identified only one fourth of the diabetic patients expected, and the next step has been the attempt to find the missing patients. There are two sources. Some may have occurred in those individuals who died of other causes before developing

of diabetes is undoubted, for in each consecutive thousand of our cases, our cases compared with those of other clinics, and in American clinics as compared with European clinics the incidence behavior is essentially the same. From these two factors the potentiality for developing diabetes in parents and children has been predicted.<sup>9</sup>

Although these data seem obviously convincing, besides dealing with a population whose status is changing—once diabetic always diabetic, but once nondiabetic not always nondiabetic—another source of confusion is possible. Dependent on case histories, some indi-

TABLE 2—Incidence of Diabetes in a Control, Diabetic and Twin Population

Type of Population	Number of Individuals	Per Cent of Siblings With Diabetes
Control	153	0.6
Diabetic	523	0.0
Dissimilar twins	13	10.0
Similar twins	13	70.0

viduals classified as diabetic may be nondiabetic and some classified as nondiabetic may actually be diabetic. Therefore, a series of control and another of diabetic families were studied for symptoms and tested with routine blood sugar tests and with tolerance tests.

Relative hyperglycemia was characteristic of the families of diabetic individuals, no matter whether the examinations were routine or by tolerance test. 14 per cent in the 169 persons tested by routine and 25 per cent in the 95 persons examined by tolerance test were diabetic in type, as compared with 2 per cent in the control population. These cases were not classified as diabetic and not utilized in our calculations, because we have dealt only with clinical cases of diabetes and not with potential diabetes. Time alone will reveal the significance of the latter observations. The tested selected families on the basis of clinical diabetes confirmed the consecutive case histories.

CONCLUSIONS

- 1 Each member of similar twins developed diabetes more than four times as frequently as each member of dissimilar twins, namely, 70 per cent of the former and 16 per cent of the latter.
- 2 The incidence of diabetes in the relatives of a diabetic population is significantly greater than in a nondiabetic group.
- 3 Mendelian ratios were found in a consecutive series of diabetic cases and in a selected mendelian population tested by histories and blood sugars.
- 4 Many blood relatives of diabetic patients have symptomless hyperglycemia the significance of which is unknown. These instances occurred when one would expect diabetes to develop according to mendelian inheritance.
- 5 We believe that the potentiality for developing diabetes is transmitted as a simple mendelian recessive trait and that the secondary factors which permit the expression of the gene can best be studied among predestined diabetic patients, namely, homologous twins of diabetic patients and the offspring of two diabetic patients.

## Clinical Notes, Suggestions and New Instruments

### DETECTION OF FREE ACID IN PATIENTS WITH SUSPECTED ANACIDITY

HEINRICH NECHELES M D AND LOUIS SCHEMAN M D CHICAGO

In examining a great number of patients with peptic ulcer or with subtotal gastrectomies, one is often faced with the problem of an apparently complete anacidity and a lack of response of the acid secretion of the stomach even to histamine in patients who complain about heartburn, belching of sour material, and the like. Sometimes examination of the stomach contents of such persons right after sampling but before filtration reveals a strong positive reaction for free acid (Topfer's reagent) on the surface of the mucous material only. This soon disappears, especially after filtration. Such cases cannot be called anacid but under the conditions of an ordinary stomach test would so appear. Evidently the little free hydrochloric acid that is present combines quickly with the mucus which in most of these cases is abundant. In other cases, regurgitation from the duodenum is the neutralizing factor. We therefore devised a method by which the reaction of each small sample of gastric contents can be tested as soon as it passes out of the stomach.

Diagram of apparatus devised to test sample of gastric contents as soon as it passes out of stomach tube

The apparatus used is here illustrated. It consists of a glass T tube, the vertical arm of which is wide enough to hold a stopper with a bore. The lower end of a buret is used, the glass tube below the stopcock being pushed through the bore of the stopper. The opening of this glass tube is made as narrow as possible. One end of the T piece is connected to a suction device with a mercury manometer and needle valve. The other end of the T tube is connected to the stomach tube. The container above the stopcock is filled with Topfer's reagent. Small sealed glass tubes with various concentrations of hydrochloric acid and Topfer's reagent may conveniently be attached alongside the horizontal part of the T tube to read the concentration of free acid in the gastric juice. The base of the wooden stand on which the T tube rests is painted white. As the suction works and gastric contents appear in the T tube, the stopcock is opened, permitting a drop of reagent to come in contact with the stomach juice and notes are taken of the color reaction. Mucus, bile and pure stomach juice can thus be tested separately before neutralization takes place. This method has proved so successful in our hands that it may be of interest to others. Since we have begun to use it, we have been able to demonstrate free acidity in eighteen out of twenty patients with subtotal gastrectomies.

Twenty-Ninth Street and Ellis Avenue

From the Department of Gastro-Intestinal Physiology, Nelson Morris Research Institute, Michael Reese Hospital.

We are indebted to Drs. Alfred and Sigfried Strauss and Jacob Meyer for sending us patients for these tests.

This study was carried on by the aid of a grant from the Louis L. Cohn and Kuppenheimer funds to the Stomach Group of the Michael Reese Hospital.

### DEATH FOLLOWING PHRENICECTOMY

JOHN WEBER, M D, GLENDALE, CALIF.

Death following phrenicectomy, a relatively simple operation, is rare. In Sauerbruch's series of 300 operations there was only one operative death.<sup>1</sup> A branch of the short thyrocervical artery, sometimes encountered in the fat between the fascia beneath the platysma muscle and the scalenus anticus muscle, was severed. In order to check the hemorrhage the subclavian artery was ligated but the patient died.

This report describes a cause of death following this operation, which I believe has not previously been related in the medical literature. I wish also to suggest a second operation which might have saved the patient's life.

A man, aged 33, unmarried, an American, gave a history of chronic pulmonary tuberculosis of ten years' duration, six of which he had spent in bed. Physical examination revealed a far advanced, active fibrocaseous tuberculosis of the right lung with cavity formation involving practically the entire upper lobe. There was also a moderate amount of tuberculous infiltration of the upper lobe of the left lung. Roentgenograms of the chest confirmed the physical examination and the sputum showed myriads of tubercle bacilli. During each twenty-four hour period the patient raised from 5 to 6 ounces of mucopurulent sputum. The temperature remained practically normal with bed rest. His weight while stationary during the six months preceding operation, was 30 pounds (13.6 Kg.) below the average for his age and height.

Artificial pneumothorax was attempted five times unsuccessfully. A phrenicectomy was advised, to be followed later by a paravertebral thoracoplasty.

Phrenicectomy was performed and was followed by gradually increasing dyspnea, cardiac failure and death in six days. It was not possible to obtain postoperative roentgenograms of the chest, but physical examination following operation demonstrated an elevation of the right diaphragm from the sixth to the fourth rib in the mammary line and a deviation of the heart into the left side of the chest, measuring 4 cm. The resultant mechanical interference with cardiac movement was the cause of death.

### BENEFIT OF PHRENICECTOMY

Unfortunately for the patient I did not consider the benefit that might have followed a left phrenicectomy, or, better still, a simple crushing of the phrenic nerve with a hemostat combined with cutting of the accessory nerves. The latter operation would have caused only a temporary paralysis of the left diaphragmatic leaf. If either of these operations had been performed, the left diaphragm probably would have ascended sufficiently upward into the thorax to force the heart back into its normal position, thus relieving the complication. I believe now that the second operation should be performed in the presence of this particular complication.

Bilateral phrenicectomy or simple phrenicotomy has been used with marked success for persistent singultus and to permit artificial respiration in diaphragmatic tetanus by Sauerbruch,<sup>2</sup> Kroh,<sup>3</sup> Jehn,<sup>4</sup> Lehman<sup>5</sup> and Dehler and Stern.<sup>6</sup> Unfortunately the value of this relatively simple operation, particularly for the relief of persistent and often fatal hiccups, is not generally appreciated. It will not only effect a cure when all other measures have failed but also causes, as a rule, only a temporary embarrassment of respiration.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.  
CHICAGO

*NOTE—In their preparation these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by the various members are incorporated in the final draft prepared for publication. The series of articles will be continued from time to time in these columns.—Ed*

#### THERAPY OF FRESH ACCIDENTAL WOUNDS

The therapy of fresh accidental wounds must meet four general indications: check hemorrhage, treat shock, render the wound aseptic and put the affected part at rest, and restore the part to the greatest possible degree of usefulness.

Hemorrhage may be checked by pressure (tourniquet, bandage), elevation or heat (120° F). See also "Therapy of Bleeding."

Shock may be treated by analgesia, recumbency and heat. See also "Circulation Deficiency Crises."

The wound should be rendered aseptic and closed according to approved surgical principles as soon as this has probably been accomplished. An aseptic wound is one that heals by first intention without signs of excessive inflammation and without constitutional disturbance. It need not necessarily be sterile, i. e., completely free from micro-organisms. Asepsis is a clinical concept, sterility, a bacteriologic term.

As an emergency dressing, the wound should be covered with the cleanest (most nearly sterile) possible absorbent material. The skin surrounding the wound (but not the wound itself) may be painted with antiseptic solution of iodine (2 per cent in 50 per cent alcohol). As soon as possible thereafter, with aseptic (operating room) technic, (1) contamination should be removed, (2) culture medium for micro-organisms should be removed, (3) the affected part should be immobilized, (4) local tissue reaction should be improved and (5) systemic resistance should be improved.

1 Contamination should be removed as thoroughly as possible, meaning at least all visible dirt. First, the part surrounding the wound is scrubbed with soap, brush and sterile water (and with ether or gasoline if nonsaponifiable fatty matter is a contaminant, while the wound is kept covered with sterile gauze). Then the skin surrounding the wound may be painted with antiseptic solution of iodine. Secondly, the wound itself should be cleansed with neutral soap and gently wiped with sterile gauze sponges and irrigated with sterile water. Ether or gasoline may have to be used to remove soap-insoluble grease. Solution of hydrogen dioxide has quite a cleansing value for dirt ground into flesh and for the removal of crusts and clots, but it should not be used unnecessarily. Chemical disinfectants probably have no place in this cleansing process; they are apt to damage tissue cells more than they harm micro-organisms. Good wound healing depends as much on the vitality of the cells on the wound surface as on the absence of micro-organisms, and probably more. If anesthesia is required for the treatment of the wound, nitrous oxide-oxygen inhalation is the agent

of choice, as it aggravates shock less than any of the other anesthetics.

2 All culture medium for micro-organisms should be removed, and its accumulation prevented.

(a) Debridement removes all undoubtedly irretrievably damaged tissue. The aim should be to secure as nearly as possible fresh and clean wound surfaces so that they may heal by primary union and without drainage. All hemorrhage should be checked, for a hematoma means culture medium and inevitable infection.

(b) When a complete debridement is inadvisable because of the functional importance of the tissue that would have to be sacrificed, a chance may be taken that the tissue might be viable and the wound closed with the exception of a small drain, which should be removed as soon as possible. Drainage is not so much for the purpose of serving for the escape of micro-organisms as for the removal of fluid exudate, the accumulation of which under these circumstances determines infection.

(c) The Carrel-Dakin technic of contaminated wound disinfection should be instituted in very extensive, grossly mutilated wounds with much more or less devitalized tissue, after as thorough debridement as advisable and after the wound has first been converted into an open surface down to its very depth. Secondly, irrigating tubes are inserted into every nook and corner of the wound, and the surface is so postured as to make a trench in which surgical solution of chlorinated soda may be kept in contact with the tissue as thoroughly as possible. Fresh solution is introduced into the wound at intervals of every two hours, because by that time the fluid will have lost its disinfecting value. The chief virtue of this solution is that it renders necrotic tissue unsuitable for the growth of micro-organisms and favors its solution. The skin surrounding the wound should be protected with petrolatum, because the fluid is irritating. As soon as all necrotic tissue has been removed and the wound looks clean, an attempt at secondary union should be made, the wound surfaces being freshened if necessary. The making of bacterial counts from the wound surfaces is helpful to determine the amount of infection present.

3 The affected part should be absolutely immobilized immediately after the injury to prevent as much as possible the dissemination of micro-organisms. Since it is impossible to sterilize such wounds, the prevention of systemic invasion, as well as of extensive spread to surrounding tissues, depends on the speediest possible formation of a fibrin network (which occurs within half an hour) and its protection against rupture so that it may serve as scaffolding for the ensuing round cell infiltration. The immobilization also favors inception of healing. As soon, however, as no further danger of spread of infection is present and sufficient union of tissue has occurred to permit motion without rupture, gradual resumption of function should be insisted on.

4 Local tissue reaction should be improved, chiefly by antagonizing edema, the part being elevated if possible and proximal constriction being prevented, but allowance should be made for a certain amount of inevitable swelling by not drawing the sutures tight and by rather loose bandaging. Evidence of infection means immediate recourse to hot, moist dressings and the earliest possible release of accumulated fluid.

5 Systemic resistance should be improved. Because of the seriousness of tetanus, with all wounds that are

deep and hable to harbor unremovable earth or street dirt, tetanus antitoxin (1,500 units unless the wound is very extensive, then 5,000 units) should be administered immediately. Still better is the combination of tetanus and gas bacillus antiserum in the prophylactic treatment of all severe wounds. In especially endangered wounds, a second dose should be given within a week. A dose should also be administered before the undertaking of a secondary operative procedure on such a wound. The antitoxin is not required in slight, superficial or uncontaminated cuts and bruises in which mere iodization suffices to destroy the contaminating micro-organisms, even though it may delay the healing process.

Needless to say, an abundance of sleep and a nutritious diet, suitable for the individual, are of importance in securing the promptest possible recovery.

Efficient treatment of any systemic abnormality, be this syphilis, or diabetes, nephritis or anemia, will also contribute to expedite healing. Every surgical case is, therefore, also a medical case.

## Council on Pharmacy and Chemistry

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

**DIODRAST**—35 diodo-4-pyridone *N*-acetic acid and diethanolamine —  $C_8H_{10}ONI \cdot CH_2COOH + NH(CH_2CH_2OH)_2$  — A mixture or a loose combination (in solution) of diethanolamine,  $NH(CH_2CH_2OH)_2$ , and 35 diodo-4-pyridone-*N*-acetic acid,  $C_8H_{10}ONI \cdot CH_2COOH$  in equimolecular quantities. Diodrast contains approximately 49.8 per cent of iodine.

**Actions and Uses**—Diodrast is proposed as a contrast agent for intravenous urography. Local reactions about the site of injection are said usually not to occur or to be very mild when they are observed, systemic reactions occur occasionally. The latter consist chiefly of flushing of the skin with a sense of warmth, less often transient nausea, vomiting, erythematous eruptions, respiratory distress and cyanosis may occur. These side effects are said usually to subside within a few minutes to an hour or so without special therapy, but the skin eruptions may rarely persist for several days. In animals diodrast in doses equivalent by weight to those used clinically has been found to lower the blood pressure for a period of about two hours, this slowly returns to normal and may be followed by a secondary rise at the same time respiration is stimulated. These actions have been reported also to occur in the human being. Fasting and dehydration of patients preliminary to injection of the drug are widely employed. The optimum time for taking roentgenograms varies between five and fifteen minutes after injection in individuals with normal kidney function (usually one exposure is made after ten minutes and a second after a further interval of ten or fifteen minutes). When renal function is impaired, this interval is proportionately longer (thirty minutes or more). Pressure over the bladder is employed by some clinicians; this is released immediately before the first exposure and is replaced until the next. The use of the drug is contraindicated in patients with severe liver disorders, nephritis, tuberculosis or hyperthyroidism and great care must be exercised in cases of uremia. Preliminary renal and hepatic function tests are advisable in suspected cases. Caution should be exercised in cases in which a reduction in blood pressure would be dangerous or otherwise undesirable.

**Dosage**—Twenty cc of a solution containing 7 Gm of diodrast previously warmed to body temperature is injected slowly usually into the cubital vein. Children are given correspondingly smaller doses. Diodrast is administered intravenously in the form of an aqueous solution, each cubic centimeter contains 0.35 Gm.

Manufactured by Winthrop Chemical Co., Inc. New York U. S. Patent and Trademark applied for.

**Diodrast Sterile Solution** (35 per cent weight/volume) 10 cc size ampule 10 cubic centimeters contains diodrast 3.5 Gm.

**Diodrast Sterile Solution** (35 per cent weight/volume), 20 cc size ampule 20 cubic centimeters contains diodrast 7.0 Gm.

Diodrast responds to the following identity tests. Dilute about 10 cc of diodrast solution with an equal volume of water, add an excess of diluted hydrochloric acid, collect the liberated 35 diodo-4-pyridone *N*-acetic acid on a filter paper, wash and dry at 100°C. It melts with decomposition between 245 and 249°C (the melting point bath previously heated to 200°C). (Save the filtrate \*). Transfer about 0.1 Gm of the resultant acid to a small hard glass test tube containing a piece of sodium (about the size of a pea) previously melted after the first violent action has ceased, heat until the contents of the test tube are decomposed, vapors of iodine are evolved, the tube and contents are allowed to cool, add 10 cc of water, boil the mixture for a few minutes, filter through paper and divide into two portions. To one portion add 1 cc of concentrated nitric acid, boil, cool and add 1 cc of silver nitrate solution; a curdy yellow precipitate results, insoluble in an excess of stronger ammonia water. To the other portion add a few drops of fresh ferrous and ferric sulphate solutions, heat to nearly boiling and carefully neutralize with diluted hydrochloric acid; a finely divided blue precipitate results. Concentrate the original filtrate from the foregoing \* cool in ice water, filter, evaporate to syrupy consistency, add 5 cc of alcohol, neutralize the mixture carefully with normal sodium hydroxide using litmus as an indicator, filter and increase the volume of the filtrate to about 10 cc with absolute alcohol, add 1 Gm of trinitrophenol (picric acid), heat to boiling and finally cool in ice water, collect the resulting diethanolamine trinitrophenolate on a filter paper, recrystallize from alcohol and dry in a desiccator over sulphuric acid under a partial vacuum; it melts at 245 to 249°C with decomposition (the melting point bath previously heated to 200°C).

Dissolve about 1 Gm of the resultant acid in 1.5 cc of a 10 per cent solution of sodium hydroxide and make up to a volume of 3 cc. A clear colorless solution results. To the foregoing solution add 7 cc of water and an excess of diluted hydrochloric acid, filter and divide the filtrate into two portions. To one portion add 1 cc of chloroform and 0.1 cc of ferric chloride solution, no coloration is imparted to the chloroform layer (absence of free inorganic iodides). To the other portion add 1 cc of barium chloride solution, no turbidity results (sulphate).

**Diodo-4 pyridone *N*-acetic acid**, a component of diodrast, responds to the following tests for identity and purity.

**Diodo-4 pyridone *N*-acetic acid** occurs as a white crystalline odorless powder, slightly soluble in water, practically insoluble in organic solvents. It melts at 245 to 249°C with decomposition (the melting point bath previously heated to 200°C).

**Diodo-4 pyridone *N*-acetic acid** responds to identity and purity tests previously described under diodrast, except those dealing with diethanolamine.

Dry about 1 Gm of diodrast acid component 35 diodo-4 pyridone *N*-acetic acid accurately weighed to constant weight at 100°C, the loss in weight does not exceed 1 per cent. Transfer about 1 Gm of Diodrast acid component accurately weighed to a 500 cc Kjeldahl flask and determine the nitrogen content according to the official method described in Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists, third edition, page 20, chapter 2, paragraph 22. The percentage of nitrogen corresponds to not less than 3.3 nor more than 3.6 when calculated to the dried substance. Transfer about 0.5 Gm of the diodrast acid component to a Parr sulphur bomb, determine the iodine content by the Lemp and Broderson Method (*J. A. Chem. Soc.* 39 2069), the amount of iodine found corresponds to not less than 62.3 per cent nor more than 63.2 per cent when calculated to the dried substance.

#### DIODRAST STERILE SOLUTIONS

Diodrast solution is prepared by neutralizing 35 diodo-4 pyridone *N*-acetic acid in water with an equimolecular quantity of diethanolamine. The mixture thus formed in solution (not isolated in solid form) is very soluble in water.

Diodrast solution occurs as a clear and nearly colorless liquid. It is neutral to litmus. Diodrast solution is incompatible with mineral acids. The specific gravity is from 1.180 to 1.190 at 25°C.

Place 10 cc of diodrast solution accurately measured in a suitable tared platinum dish, evaporate to dryness on the steam bath and ignite; the residue does not exceed 0.10 per cent.

Transfer 10 cc of diodrast solution accurately measured to a suitable glass stoppered erlenmeyer flask, neutralize with normal hydrochloric acid, adding a very slight excess, cool the flask and contents to about 5°C, collect the precipitate formed in a tared gooch crucible, wash with cold diluted acid solution, dry to constant weight at 100°C, the weight of 35 diodo-4 pyridone *N*-acetic acid obtained corresponds to not less than 2.7 Gm nor more than 2.8 Gm. The free acid corresponds to the standards given under diodrast.

**Note**—The assay by precipitation with a mineral acid is roughly approximate; it is important that as nearly exactly the specified amount of diodrast solution as possible be used because the solubility of the 35 diodo-4 pyridone *N*-acetic acid precipitate varies. This assay method of standardization is therefore at best approximate and must be considered tentative until such time as more accurate analytic procedure is available.

**THIO-BISMOL** (See New and Nonofficial Remedies, 1934, p. 123).

The following dosage form has been accepted:

**Ampoules Thio Bismol** 2 Gm. Each ampule contains 2 Gm (30 grains) of thio-bismol to be dissolved in 20 cc of sterile distilled water before administration.

**METHENAMINE** (See New and Nonofficial Remedies, 1934, p. 212).

**Urotropin**—A brand of methenamine—U. S. P.

Manufactured by Schering & Glatz, Inc. New York. U. S. trademark 269 754.

**Urotropin Tablets** 5 grains (0.3 Gm.)

**Urotropin Tablets** 7½ grains (0.5 Gm.)

**POLLEN EXTRACTS-SWAN-MYERS** (See New and Nonofficial Remedies, 1934, p 40)

The following dosage form has been accepted

*Mixed Ragweed Pollen Extract Decimal Dilution Set* A mixture of equal parts of short and giant ragweed pollen extract marketed in packages of five vials containing respectively 5 cc of a 1:100,000 dilution (10 pollen units per cubic centimeter) 5 cc of a 1:10,000 dilution (100 pollen units per cubic centimeter) 5 cc of a 1:1,000 dilution (1,000 pollen units per cubic centimeter) 5 cc of a 1:100 dilution (10,000 pollen units per cubic centimeter) and 5 cc of a 1:10 dilution (100,000 pollen units per cubic centimeter)

Manufactured by the Abbott Laboratories North Chicago Ill No U S patent or trademark

## Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING GENERAL DECISION  
RAYMOND HERTWIG Secretary

### SWEETS IN THE DIET, ESPECIALLY OF CHILDREN

The adequate nutrition of children and adults requires careful selection of foods both as to kind and as to quantity. Each type of food has a proper place in the diet. A well balanced diet, including ample proteins, fats, carbohydrates, minerals, vitamins and roughage, is one of the prime requisites for growth and health. Sweets consisting essentially of sugars are likely to be taken in excess because of their highly pleasing flavor. They supply energy only for body activity. Although sweets are wholesome and valuable foods when given their proper place in the balanced diet, they contribute few or none of the structural components required for good nutrition. Common concentrated sweets used to excess are harmful, especially in the case of children, so far as they impair the appetite for other highly necessary foods and lead to a reduced intake of milk, eggs, fruits, vegetables, meat and cereals.

Food advertising that obscures the facts of good nutrition by encouraging too liberal use of sweets should be condemned.

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

#### CALIFORNIA HOME BRAND CHILI SAUCE

*Manufacturer*—California Conserving Company, Inc., San Francisco

*Description*—Chili sauce containing tomatoes, sucrose, distilled vinegar, onions, sodium chloride, cassia, mace, cloves, garlic, celery seed chilies and pepper.

*Manufacture*—Vine ripened sorted tomatoes, specially grown, are spray washed, scalded, again spray washed, hand peeled and cored, and cooked with the named spices (in cotton bags), sugar and salt for twenty minutes. The spice bags are removed, distilled vinegar is added, steam is turned off and a sample is drawn for laboratory test. When refractometer, mold count, color and consistency tests indicate that the product has reached the required standards, the mass is automatically bottled at 88 C and cooled.

*Calories*—12 per gram 34 per ounce

*Claims of Manufacturer*—The speed of handling tomatoes from field to finished product keeps mold and bacteria at a minimum and protects tomato flavor and color.

### STOKELY'S FOR BABY SPECIALLY PREPARED STRAINED TOMATOES

SEASONED WITH SALT

*Manufacturer*—Stokely Brothers & Company, Inc., Indianapolis

*Description*—Pasteurized sieved tomatoes, seasoned with salt, largely retaining the natural vitamins and minerals.

*Manufacture*—Sound tomatoes at the height of color and flavor are washed in troughs of running water, rolled through reel washers equipped with water sprays for thorough rinsing, sorted and trimmed on continuous belts, and the underripe and overripe fruit eliminated. The selected clean tomatoes are sliced, passed through a preheating chamber containing an atmosphere of steam, comminuted, canned and processed as described for Stokely's Strained Green Beans (THE JOURNAL, May 26, 1934, p 1763).

Analysis (submitted by manufacturer) —	per cent

*Calories*—0.2 per gram 6 per ounce

*Vitamins*—Selection of vine ripened tomatoes, vacuumizing to remove air naturally in the tomatoes, the exclusion of air throughout the preparation and processing of the juice, insure a high retention of the natural vitamins. An excellent source of vitamin C and a good source of vitamins A and B.

*Claims of Manufacturer*—Supplementary to the infant milk diet, and valuable for children and adults on soft diets. Has smooth consistency and supplies desirable bulk without roughness. The straining renders the nutrient content readily available for digestion. Scientifically prepared to retain in high degree the natural flavor, mineral and vitamin values. Seasoned to bring out full flavor and packed in enamel lined cans. Requires only warming for serving.

*Manufacturer*—The American Agricultural Chemical Company, Detroit

*Description*—Plain unsweetened, unflavored gelatins made from hard bones green salted calfskin trimmings and frozen pigskins graded on the basis of jelly strength for special uses.

*Manufacture*—Bones after leaching with hydrochloric acid to remove the mineral phosphate and washed calfskins are immersed in a milk of lime solution for several weeks. After removal they are washed and placed in boiling water in tanks. The thawed pigskins are treated with hydrochloric acid, washed and placed in the boiling water vats. The ossein of the bone and the collagen of the skins are hydrolyzed and a solution of gelatin is formed. Several runs of which are taken off at increasingly higher temperatures the runs decreasing in gel strength. These various runs are blended in accordance with predetermined schedules concentrated in a vacuum pan filtered and jellied into a flexible sheet on a refrigerated belted conveyor. The sheet is cut placed on aluminum wire frames and dried.

to 10 12 per cent moisture content. The dried gelatin is laboratory tested, ground, screened and placed in paper lined barrels for shipment. The ground gelatin of the different runs may be blended to produce any one of the market grades. Keystone Silver Label Gelatin is left in sheet form and wrapped in individual packages.

## ORGANIZED MEDICINE AND MEDICAL CARE

In some places confusion seems to exist regarding the attitude of organized medicine in relationship to some of the proposals for changes in the nature of medical practice. The confusion has been worse confounded by the precipitate and widely publicized action taken by the American College of Surgeons at a specially called meeting of its Board of Regents in Chicago on June 10, one day before the opening of the annual session of the American Medical Association in Cleveland, at which, as had been announced well in advance, the whole profession of the United States proposed to consider this subject. No doubt, the rebuke administered to the Board of Regents of the American College of Surgeons by the House of Delegates of the American Medical Association was well warranted, and the unanimous approval which greeted the passing of the resolution that the Board of Trustees and the Judicial Council of the Association request an explanation and justification from the Board of Regents was testimony to the manner in which the medical profession in general viewed this action. Even though it may be established that the consideration of this topic by the Board of Regents at such a time was unthinking and unpremeditated, its effect has been such as to give the American medical profession serious concern. Editorials published in newspapers indicate how the propagandists who oppose the policies of organized medicine have taken advantage of this action of the Board of Regents of the American College of Surgeons. THE JOURNAL has called attention repeatedly to the fact that representatives of the Milbank Fund, the Twentieth Century Fund and the Rosenwald Fund have made and are making it their major function to put over a system of social medicine in this country. Mr. E. A. Filene, founder of the Twentieth Century Fund, indicated recently that these three foundations intend to organize particularly to put over their plans. Unless the medical profession speaks with one voice the possibilities of successful opposition are threatened. Since members

of such special societies within organized medicine as the American College of Surgeons and the American College of Physicians, and similar specialistic organizations, are all either members or Fellows of the American Medical Association, the directing councils, bureaus and regents of such bodies should be made to realize by their membership that the majority of physicians of the United States prefer to express their views on economic, political and governmental questions through organized medicine, and that the function of the specialistic societies should be limited to proper consideration of scientific and educational questions.

The considerations that have here been set forth should not lead any one to believe that the American Medical Association, representing 100,000 physicians in the United States, is opposed to all change in the nature of medical practice or to properly controlled experiments in providing medical service that may be set up in any city, county or state. Organized medicine does stand for certain basic principles in any form of medical practice which are fundamental to a maintenance of the high quality of medical care now given to the vast majority of the American people. Even the most radical proponents of change are willing to grant that the standards of medical care in the United States today are higher than those to be found in any other country in the world, regardless of the system of medical care under which it operates.

The House of Delegates of the American Medical Association, following a long executive session, set forth ten principles to guide medical practice and to form the basis for any experiment that may be contemplated. These principles were published in the proceedings of the House of Delegates in THE JOURNAL for June 30, page 2200. It is proposed to discuss these principles individually in further comments in THE JOURNAL from time to time. As was well set forth by the special committee of the House of Delegates which drew up these principles, a reasonable observance will remove many of the disturbing influences from any experiment, particularly as these principles are planned to focus the attention in all medical service on the quality as well as on the costs. These principles were planned to circumvent the interest of politicians, commercial promoters and propagandists whose activities in relationship to new forms of medical practice are not wholly unselfish. The principles are planned to protect the character of the service to be given. They will maintain the personal relationship between physician and patient, which keeps medicine a profession.

On the principles adopted by the House of Delegates the American medical profession must stand, and in their favor it must speak with a united voice. This is no time for the activities of the individual who seeks personal prestige and political preferment as a reward for contributed leadership. In most of the great nations of the world, social medicine has been the panacea proffered by politicians and philanthropists.

against social unrest. Let us learn from the experience of those who have tried and who, in many instances, have failed. Let us not be misled by high sounding phrases and insidious diction. Let us beware of generalizations which lead to disaster when the details of their fulfillment become apparent. Let us consider carefully, act with caution, reserve judgment, and speak with one voice for the truth.

### CHOLESTEROLEMIA AND THYROID DISORDER

Ever since the development of methods for the more ready estimation of cholesterol in small samples of blood, data have been accumulating in increasing numbers regarding the occurrence of this blood lipid. The amount present is evidently subject to marked variations even in conditions of health. This is apparently not due to differences in cholesterol intake, for the latter ordinarily has relatively slight influence on the level of blood cholesterol. For some reason it seems to be influenced by the general state of health and nutrition, but until recently even experts in the study of blood were forced to confess that "our knowledge of the factors that determine the level of the various lipid constituents in the blood in disease is pitifully meager"<sup>1</sup>. The values for healthy persons fluctuate between 0.13 and 0.20 per cent. According to Peters and Van Slyke, increase in blood cholesterol, when it occurs in any disease, is more correctly to be associated with some functional disturbance connected with the disease than directly with the malady itself. It is of only secondary significance. High figures for blood cholesterol have long been associated with certain types of kidney disorder, the content sometimes reaching more than 500 mg per hundred cubic centimeters of plasma. More recently, variations in blood cholesterol have been associated with variations in the activity of the thyroid.

Although there has appeared to be a lack of clear relationship between the basal metabolic rate and the blood cholesterol value (during fasting) in the absence of thyroid disturbance,<sup>2</sup> the observations point to the desirability of more intensive study of the subject. Hurvath<sup>3</sup> of the Lahey Clinic in Boston has summarized a large experience. It indicates that the blood cholesterol is low in toxic thyroid states and is brought to a normal level partly by preoperative treatment but chiefly by subtotal thyroidectomy. There seems to be a reciprocal relationship between the average elevation of the basal metabolic rate and the average lowering of the blood cholesterol level in toxic goiter, which is further confirmed. In myxedema and other equally well defined cases of hypothyroidism, hypercholesterolemia

is a quite constant finding. Accordingly Hurvath states that hypercholesterolemia, when not explainable on any other basis, may be considered as possibly of thyroid origin and is a rational indication for thyroid administration.

The finding of hypercholesterolemia, in the absence of its few other common causes, points more specifically to thyroid deficiency than does the finding of a low metabolic rate. Finding both renders the possibility of thyroid deficiency extremely likely. The relationship between the blood cholesterol and the basal metabolism is usually reciprocal when they undergo change as the result of variations in the activity of the thyroid gland or thyroid substance in the body. Accordingly it seems warranted to assume that the blood cholesterol provides another variable that may be used as a guide in the treatment of thyroid disease.

### IS CANCER BECOMING MORE PREVALENT?

For a number of years it has been much debated whether or not a real increase has occurred in the incidence of cancer throughout the civilized world. The method employed has been statistical and therefore based as a rule on observations made by a number of different people under different circumstances. The reliability of the conclusions thus deduced depends fundamentally on two components, which are applicable also to any other set of medical or vital statistics—the accuracy and completeness of the original observations and the statistical interpretation and dissociation of modifying factors.

The diagnosis and recording of cancer, especially of the internal organs, have improved markedly in the last few decades but, as every practicing physician and every pathologist knows, the distribution by organs differs according to whether the observations are made by a physician or by a pathologist. Wells<sup>1</sup> noted these points in 1927. The percentage of necropsies is increasing with consequent modification of recorded cancer mortality and correct assignment of distribution. In regard both to accuracy and to completeness of original cancer observations there is a constant change, and comparative statistics based on recorded morbidity and mortality must take this factor into account.

Probably of even greater moment than the changing accuracy and recording of original cancer are the methods of handling the statistics. This fact has not lacked recognition and has been discussed and treated in various ways in numerous articles. Wood,<sup>2</sup> for example, in analyzing the reliability of cancer statistics, says "An examination of the death certificates of cancer cases showed that on 22 per cent of many hundred certificates the 'duration' of the cause of death

<sup>3</sup> Hurvath L. M. *Blood Cholesterol and Thyroid Disease*. II. *Arch. Int. Med.* 52: 86 (July) 1933. III. *ibid.* 53: 763 (May) 1934.

<sup>1</sup> Wells H. G. *Cancer Statistics as They Appear to a Pathologist*. *J. A. M. A.* 88: 399 (Feb. 5) 476 (Feb. 12) 1934.

<sup>2</sup> Wood H. B. *Reliability of Cancer Statistics*. *Am. J. Surg.* 18: 31 (Oct.) 1932.

exactly corresponded to the two dates showing the length of treatment. To quote the duration of illness as given on death certificates, therefore, is misleading. There was a preponderating guess that the duration of the disease was one year, or similar designation." He says further "One of the largest hospitals in the state (Pennsylvania) during six years showed a decrease in lip and tongue cancers, mouth cases showed no change, and the larynx cases doubled, stomach cases quadrupled, rectal cancers increased one half and cervical one sixth. These simply show an experience and do not indicate any trend of cancer development." It is thus possible to testify to the flimsy foundation on which such statistics are often based. At least the error possible should be recognized and allowance made.

The crude death rate, i. e., the deaths from cancer annually per hundred thousand of the total population, does not furnish a sound base for the decision as to fact or degree of cancer increase. Thus, as has been repeatedly pointed out, the age groups from which the statistics are drawn modify the interpretation. A striking example is mentioned by Macklin,<sup>3</sup> who says "In 1928 Prince Edward Island had a cancer rate of 114, while Saskatchewan had a rate of only 55, or less than half that of the former province. When, however, we consider the age of the population in the two provinces, we see that in the one with the high cancer rate, 31.5 per cent of the inhabitants were over 40 as contrasted with 19.6 per cent in the province with the low cancer rate."

On the other hand the mere variation in or increase of individuals in the upper age groups probably fails to account wholly for the reports of cancer increase. In the group of Metropolitan Life Insurance Company<sup>4</sup> policyholders, for example, even when the 1930 and 1931 cancer death rates are standardized for age, a large increase in the rate was found. "Further," the report states, "no such marked increase in the death rate has been observed in the mortality from cardiac disease, chronic nephritis and cerebral hemorrhage, all of which, like cancer, are diseases of the older ages."

An ingenious, if not perhaps conclusive, method of analysis has been described by Bolduan and Weiner.<sup>5</sup> Their statistics were based on the cancer mortality in New York City, which they divided into "visible cancer," i. e., of the skin, breast, buccal cavity and female genitals, and other forms. When adjusted for age distribution they found practically no change in the death rate from visible cancer in a thirty year period, though the death rate charged to cancer generally showed an upward trend. They believe, therefore, that this evidence seems to "warrant the conclusion that cancer is probably no more prevalent now, in any given age group, than it was a generation ago."

A consideration of some of the factors involved thus shows the difficulty in determining the facts clearly. Training in statistical methods is essential, equally important is a knowledge of the limitations imposed by the source of the material for analysis. No one but the physicians and the pathologists who sign the original statements can fully realize the limits of the latter, when the two qualifications are combined in one individual, the closest approach to the ideal analysis should be reached.

## Current Comment

### THE STORAGE OF VITAMINS IN THE BODY

The ability of the organism to store a surplus of some of the essentials for its proper functioning is of considerable importance. Much has been said of late about the maintenance of "steady states" in the body, that is, the protection of the latter from untoward reactions by a process of homeostasis, as Cannon of Harvard has designated it. This is the biologic device by which the temperature of the body is kept constant within narrow ranges, the reaction of the blood and other features of its desirable composition are maintained in fairly uniform condition, and still other protective adjustments are accomplished. Physiologists have long been aware of the storage of energy in the form of glycogen in the liver and muscles, likewise of readily available fats in the adipose tissues. Now it is being learned that some of the vitamins are subject to storage. This undoubtedly represents a factor of safety by furnishing a depot of supply in times of dietary shortage. Thus the protection of the body against scurvy may be potentially large or small, depending not only on abundance of vitamin C in the food intake and on its adequate absorption but also on the amount deposited in the tissues. For example, King<sup>1</sup> reported not long ago that in susceptible animals studied by him depletion follows rapidly and regularly with a scorbutic diet. External indications of the depletion appear much later. The distribution of vitamin C in human tissues is analogous to that in guinea-pigs and has been found to show such marked variations for individuals that a wide zone of depletion appears to be fairly common without external evidence of a deficiency. This intermediate zone may be physiologically significant without being recognized by casual examination. Investigations<sup>2</sup> at the University of Wisconsin in Madison show that when vitamin A in the form of halibut liver oil was fed to animals the amount of vitamin A stored in the livers was found to parallel the amount of vitamin A in the diet but that only 10 to 20 per cent of the ingested vitamin A was recovered from this organ. Much of the vitamin was destroyed in the digestive tract, but not all of the losses could be attributed to this destruction. A similar storage of

vitamin A has been described, among others, by McCoord and Luce-Clausen<sup>3</sup> of the University of Rochester, N. Y. The concentration of vitamin A in the blood is no indication of the amount that may be stored in the liver. The Rochester nutritionists venture to speculate as to the reason for this striking capacity of the liver to store vitamin A. One thinks at once of a storage to combat infection, but their results lend no support to the theory of the anti-infective value of vitamin A when supplied to animals in adult life. It should not be inferred from the foregoing that all the known vitamins are stored with equal readiness, for this is surely not the case. The important point is that it is probably advantageous to keep the reserve depots, for some of the vitamins at least, well filled with these valued requisites for perfect health and well being.

### CREATINE AND THE CARDIAC MUSCLES

Creatine is a constant component of the striped muscle tissue of all vertebrates and it occurs to some extent in other tissues. As most of the creatine in the body is present in the muscles, the content approximating an average of 0.4 per cent, there is a suggestion at least that creatine is concerned in some way with the function of the contractile tissue. This has been further emphasized through the discovery of phosphocreatine in muscle and the growing evidence that this interesting compound plays some vital part in muscular contraction. In view of these considerations it is significant that the concentrations of creatine of the left and right ventricular muscles of the heart are different, the former having the greater concentration. This has been established recently at the Western Reserve University by Seecof, Linegar and Myers.<sup>1</sup> These investigators emphasize that, in addition to embryologic, anatomic, physiologic and pathologic observations, chemical evidence is now presented pointing to the fact that the left and right ventricles are different muscles. The magnitude of the differences under discussion amounts to 30 per cent in favor of the left heart. It applies to human and animal hearts alike. The two ventricles differ not only in creatine content but also in respect to other components. Differences in glycogen, lipids, phosphoric acid, inorganic salts, potassium and calcium have been recorded. Wearn<sup>2</sup> showed variations in the number of capillaries of different portions of the heart in man and in animals. There are electrocardiographic differences between the ventricles, which may again indicate qualitative differences between the left and the right ventricle. The Cleveland investigators remark that there are probably other differences with which we are not acquainted. They also point out that the realization that the left and right ventricles (as well as other portions) of the heart are chemically different may have some value in pharmacologic and therapeutic measures as applied to the heart. Seecof, Linegar and Myers conclude that

the concept that the two ventricles are different offers a working theory, which may reconcile, in a manner better than has been possible heretofore, the functional activities with the structure and the chemical constitution of the heart. As such its value remains to be proved or disproved.

## Association News

### MEDICAL BROADCASTS Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, Central daylight saving time. The speaker will be Dr. W. W. Bauer. The next three broadcasts will be as follows:

July 19 Entertaining the Convalescent Child  
July 26 The First Month  
August 2 Dog Days

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### ARKANSAS

**Resolution on School Clinics**—The Ouachita County Medical Society, Camden, recognizing that adequate examinations of school children cannot be conducted in large groups, recently adopted a resolution announcing its future policy. School children will be supplied with the necessary forms and referred to their family physicians for examination. Only those able to pay will be charged. This policy will also affect persons wishing to be immunized against typhoid, diphtheria and smallpox. Those who are not able to pay will be immunized, but the vaccine, virus or toxin-antitoxin will be furnished by the health department as at present.

### CALIFORNIA

**The Epidemic of Poliomyelitis**—A total of 1,223 cases of poliomyelitis have occurred throughout California since May 1, the *New York Times* reported, July 1. San Francisco has had sixty-nine cases of paralysis since May 1, with six deaths. Alameda County, 113 cases with eight deaths during the same period, while, on June 25, 325 patients were being treated in the Los Angeles General Hospital and 155 were under observation. Dr. James P. Leake of the U. S. Public Health Service is in California to cooperate with health officials in combating the disease.

**Plague in Ground Squirrels**—Although no case has been reported among human beings, a recent noticeable increase in the ground squirrel population led the state board of health to make a survey of bubonic plague. The work has been concentrated in the rural sections of Kern, Tulare, Monterey and San Luis Obispo counties. Twenty-one cities and towns were visited. 162 ranches were visited and squirrels were hunted on 143. There were 3,185 squirrels shot, 34 of which were found positive for plague, of the 2,400 squirrels found dead, 106 proved positive. There were 5,304 postmortem examinations made on rodents, and twenty-four plague foci were located. Plague was not evidenced in any of the rats examined.

**Society News**—At a meeting of the Alameda County Medical Association, June 18, Drs. Mark L. Emerson, Frank H. Bowles and Archie A. Alexander discussed "The Use of Histamine as an Indicator of Cutaneous Circulation in Leg Amputations" and Drs. Robert A. Glenn and Vernon G. Alderson, amebiasis. All are from Oakland.—Dr. James W. Sherrill, San Diego, spoke on "Relation of the Glands of Internal Secretion (Other than the Pancreas) to Carbohydrate Metabolism" before the Hollywood Academy of Medicine, June 21.—Speakers before a joint meeting of the Solano and Contra Costa county medical societies in Vallejo, June

3. McCoord, Augusta B. and Luce-Clausen, Ethel M. The Storage of Vitamin A in the Liver of the Rat. *J. Nutrition* 7: 557 (May) 1934.  
1. Seecof, D. P., Linegar, C. R. and Myers, V. C. The Difference in Creatine Concentration of the Left and Right Ventricular Cardiac Muscles. *Arch. Int. Med.* 53: 574 (April) 1934.  
2. Wearn, J. T. The Extent of the Capillary Bed of the Heart. *J. Exper. Med.* 47: 273 (Feb.) 1928.

12, were Drs William C Voorsanger, San Francisco, and Fred R Fairchild, Woodland, on tuberculosis in children and appendicitis, respectively.—The cornerstone of the library of the Los Angeles County Medical Association was laid, June 21, by Dr Walter Jarvis Barlow. It is expected that the new building will be ready for occupancy about September 1.—Clarence Cook Little, ScD, Bar Harbor, Maine, discussed "The Role of Heredity in Cancer" before the San Francisco County Medical Society, July 7.

### GEORGIA

**Program for Health Chairmen**—Members of the Fulton County Medical Society presented a program in April for health chairmen of elementary and preschool associations of the Atlanta Council of Parents and Teachers, the DeKalb and Fulton County councils, under the auspices of the woman's auxiliary of the state medical association. The following physicians participated:

Lawson Thornton Posture Defects and Correction  
Launcelot Minor Blackford The Heart Damages Through Disease Avoidance  
Lewis D. Hoppe Jr., Control of Communicable Diseases in the Home and School  
William Howard Hailey Common Skin Diseases of Children  
Zachariah W. Jackson, Sight Conservation

### IDAHO

**Society News**—Drs John F Coughlin, Twin Falls, and James O Cromwell, Gooding, addressed the South Side Medical Society at Jerome, May 28, on "Staphylococcal Skin Infections" and "Infections of the Foot," respectively.—The Nez Perce County Medical Society and the Tri-County Medical Society have recently combined to form the North Idaho District Medical Society, with Drs Russell T Scott and Malcolm J McRae, Lewiston, as president and secretary, respectively.

### ILLINOIS

**Automobile Deaths Increase**—There were 2,177 deaths from automobile accidents in Illinois during 1933 as compared with 2,104 in 1932, giving a rate of 28.5 for the state as a whole as against 27.5 per hundred thousand of population in 1932. The rate for the state exclusive of Chicago was 28.8, and for Chicago, alone, 28. According to the *Chicago Tribune* at a recent meeting of the Illinois Conference on Highway Safety Legislation, which is sponsoring drivers' license and financial responsibility laws to reduce accidents, J S Baker, engineer for the National Safety Council, estimated that accidents of all descriptions have increased about 50 per cent in the first few months of this year as compared with the corresponding period of 1933. He also declared that the number of accidents is growing faster in rural than in urban areas.

### Chicago

**Dr Lederer Named Head of Department**—Dr Francis L Lederer, who has been associate professor and acting head of the department of rhinology, laryngology and otology, University of Illinois College of Medicine, has been appointed professor and head of the department to succeed Dr Norval H Pierce, who is now professor emeritus.

**Joseph A Capps Prize**—The Institute of Medicine of Chicago is again offering the Joseph A Capps Prize of \$500 to graduates of Chicago medical schools who have received the degree of doctor of medicine during the year 1932 or thereafter. The prize will be awarded for the most meritorious investigation in medicine or in the specialties. Investigation in the fundamental sciences will be considered also, provided the work has a definite bearing on some medical problem. Manuscripts must be submitted to the secretary of the Institute of Medicine of Chicago, 122 South Michigan Avenue, not later than December 31.

**Typhoid Outbreak Among Firemen**—Physicians are asked to be on the alert for patients with symptoms suggestive of typhoid and amebiasis which might result from water consumed at the fire in the Union Stock Yards, May 19. On June 25 thirty-three persons ill with typhoid had been reported to the city board of health. It was pointed out that these persons drank from cattle troughs and almost any place they found water available. The city water supply was and is safe and only certain persons of those who drank contaminated water became infected. Eighteen suspected typhoid cases were being investigated at the time of this report, most of these persons also drank water at the stockyards. Following the fire eight of the thirty-three patients were ill with diarrhea, cramps, nausea and fever for a day or two and recovered. Later however, they became ill with typhoid. Definite onset

dates of these thirty-three cases range from June 1 to June 16. Physicians are urged to avail themselves of the facilities of the laboratory of the health department when they encounter a case they suspect of being either amebiasis or typhoid.

### KANSAS

**Brinkley Thrice Runs for Governor**—Dr John R Brinkley, the so-called "goat gland" specialist, announced his candidacy for the Republican nomination for governor of Kansas, the *Chicago Tribune* reported, June 21. Brinkley has been an unsuccessful independent gubernatorial candidate on two previous occasions. His license to practice medicine in Kansas was revoked in 1930, when he was found guilty of gross immorality and unprofessional conduct.

### MARYLAND

**Society News**—Dr Arthur M Shipley, Baltimore, addressed the Caroline County Medical Society at Denton, May 16, on "Surgery of the Blood Vessels."—The Baltimore County Medical Association was addressed in Baltimore, June 20 by Drs Harry M Stein on Lung Abscess of Unusual Origin" with exhibition of case, and George H Yeager, "Passive Vascular Exercises," with exhibition of cases.

**Examination of Substandard Workers**—Physical examinations of substandard workers in specified industries have been made by deputy state health officers in a number of counties in Maryland, recently, at the request of the state commissioner of labor and statistics, with the approval of the state board of health. Required under the National Recovery Administration, the examinations are to determine the extent to which physical handicaps or infirmities constitute a disability for the particular job on which a worker is engaged. Following these examinations, persons who are physically handicapped may be certified for employment, the wage rate to be adjusted in accordance with the extent of the disability.

**Rocky Mountain Spotted Fever in Maryland**—Thirteen cases of Rocky Mountain spotted fever have been reported to the bureau of communicable diseases of the Maryland State Department of Health since the middle of April, according to the *Monthly Bulletin* for July. Two occurred in Baltimore City, three in Anne Arundel County, four in Baltimore County, and one each in Montgomery, Prince Georges, Talbot and Worcester counties. Three cases were fatal, one each in Anne Arundel, Baltimore and Montgomery counties. Two victims were children under 6 years of age and the third was a woman 24 years old. All of the patients were exposed to ticks. The child who died from the disease in Anne Arundel County had not been bitten but had crushed a tick in his hands. Preventive measures during the past year have included the inoculation of 130 children in the Somerset area of Montgomery County.

### MASSACHUSETTS

**Harvard Bans Patents**—Harvard University faculty members have voted that the patenting of discoveries or inventions bearing on matters of health and therapeutics is undesirable. As a result, Harvard scientists will not be permitted to take out such patents, unless granted dispensations by the university, newspapers report.

**Dr Overholser Appointed Commissioner**—Dr Winfred Overholser, assistant professor of psychiatry at Boston University School of Medicine and assistant commissioner in the state department of mental diseases, has been appointed commissioner of mental diseases, succeeding Dr James V May, who resigned to return to his former position as superintendent of Boston State Hospital, which he had held from Dec 1, 1917, until 1933. Dr Overholser is 42 years of age and a graduate of Boston University School of Medicine. Dr Joseph E Barrett, Taunton, has been appointed assistant commissioner to succeed Dr Overholser. He has been associated with the department for more than six years.

### MICHIGAN

**Koch Cancer Outfit Sued**—A verdict for \$25,000 was returned by a jury in recorder's court before Judge Shernian D Callender, June 12, in the suit of Alfred A Fortner against Dr William F Koch, director of the Koch Cancer Foundation, Detroit. According to the *Detroit Medical News*, Fortner alleged that Dr Koch charged him \$300 each for injections of the cancer serum when he was not suffering from cancer. In 1921 Koch was dropped from the membership of the Wayne County Medical Society for exploiting a cancer cure, the claims for which have never been substantiated. In the recent trial Fortner said he went to Koch believing he had

cancer and was treated with the serum from June to September in 1931, after which Koch advised him to discontinue the treatment and go to a hospital. Fortner then discovered he had another disease. The complaint charged Dr Koch with negligence in that he failed to inspect the infected tissue to determine the cause of trouble, that he injected a poisonous drug in the man's blood stream, and that he abandoned his patient without cause. Koch did not appear in court to testify. The attorney for Koch said he will appeal the case.

### NEW MEXICO

**State Medical Meeting at Las Vegas**—The fifty-second annual meeting of the New Mexico Medical Society will be held in Las Vegas, July 19-21, under the presidency of Dr Charles F Milligan, Clayton. Among guest speakers will be

Dr Franklin D Garrett El Paso *Texas Anaphylaxis—An Important Cause of Obscure Abdominal Pain and Digestive Disturbances*  
Dr Casper F Hegner Denver *Surgery of the Abdomen*  
Dr James A Britton Chicago *Silicosis*  
Dr James W Kennedy Philadelphia, *Indications for Vaginal Hysterectomy*  
Dr Louis A Buie Rochester Minn *Hemorrhoids*  
Dr Charles W Mayo Rochester *Appendicitis*  
Dr Hugo O Deuss, Chicago, *Blood Dyscrasias—Agranulocytosis and Acute Leukemia*  
Dr Onis H Horrall Chicago *Trauma of the Joints and Cartilaginous Repair*

### NEW YORK

**Personal**—Drs Horace Lo Grasso, Joseph P Gimbrone and Anthony J Cetola, Buffalo, were guests of honor at a dinner given by the Baccelli Medical Club at the Hotel Statler, Buffalo, June 19, marking their completion of twenty-five years of medical service. The Medical Society of Montgomery County gave a dinner, June 19, at Canajoharie, in honor of Dr Frank V Brownell, Canajoharie, who has completed fifty years of medical practice.

**Dr Wright to Head Department**—Dr Arthur W Wright, for the past four years director of a laboratory of pathology, has been appointed professor and head of the department of pathology at Albany Medical College to succeed Dr Victor C Jacobson, who resigned. Other resignations announced are those of Drs Henrietta C Horner, associate professor of neuropathology, and Ada Hazel Curry, Troy, assistant professor of bacteriology.

**Society News**—Drs Edgar A Vander Veer and James S Lyons, among others, addressed the Medical Society of the County of Albany, June 27, on "Cysts of the Gallbladder and Bile Ducts" and "Anomalies of the Urinary System," respectively. Dr Stanley E Alderson spoke, May 23 on "Acute Intestinal Obstruction."—Dr James E King, Buffalo, was elected president of the Medical Alumni Association of the University of Buffalo at the annual meeting, June 12.—Dr Howard F Rowley gave his presidential address at a meeting of the Rochester Pediatric Society, June 1, on "Observations on the Thymus Gland."—Dr William G Turner, Montreal, among others, addressed the Franklin County Medical Society at its semiannual meeting in Saranac Lake, June 13, on "Surgical Problems in Correcting Deformities."

### New York City

**Personal**—Dr Thomas A McGoldrick was appointed chief surgeon of the police department, June 12. He has been associated with the police department for twenty-five years and is also assistant professor of medicine at Long Island College of Medicine and chief surgeon at St Peter's Hospital, Brooklyn.—Associates of Dr Frederick C Holden, professor of obstetrics and gynecology, University and Bellevue Hospital Medical College, gave a dinner in his honor at Sherry's, June 1, on the occasion of his retirement from active duty at the medical school and hospital. On behalf of his colleagues, Dr Edwin W Holladay presented to Dr Holden a silver bowl. Speakers were Drs Edward A Schumann, Philadelphia, Robert L Dickinson and Joseph Brettauer.—Dr Edward Cathcart, Detroit, has been appointed associate dean of Columbia University College of Physicians and Surgeons, to succeed Dr Frederick T van Beuren Jr, who resigned. Dr Cathcart, a graduate of the University of Michigan Medical School, Ann Arbor, was until recently at the Mayo Clinic, Rochester, Minn.—Dr Menas S Gregory has resigned as director of the psychopathic division of the department of hospitals. Dr Carter N Colbert has been appointed acting head of the psychiatric staff at Bellevue Hospital to serve until civil service examinations are held for the position.—Dr David Sackin has recently been promoted to associate professor of otolaryngology at New York Homeopathic Medical College.

### OHIO

**Dr Friedlander Appointed Dean at Cincinnati**—Dr Alfred Friedlander, professor of medicine, University of Cincinnati College of Medicine, was appointed dean of the college in June, to succeed Dr Arthur C Bachmeyer, resigned. He will assume office, September 15. Dr Friedlander is a native of Cincinnati and was graduated in medicine from the university in 1895. He was associate professor of pediatrics in the college of medicine from 1910 to 1917 and has been professor of medicine since 1919.

**Grants for Research**—Grants totaling \$8,500 annually for two years have been made to Western Reserve University School of Medicine, Cleveland, for extension of research in experimental pathology, it was announced at the commencement, June 13. Of the total amount, \$3,000 annually will be contributed by Nathan G and Charles L Richman, Cleveland, \$500 annually by Richard H Kohn, Cleveland, and \$5,000 from a trust fund established by Commodore Louis D Beaumont, a former resident of Cleveland. Dr Harry Goldblatt, associate professor of pathology and assistant director of the Institute of Pathology will have charge of the work to be done under the grants, relating especially to hypertension and peritonitis.

### PENNSYLVANIA

**Survey of Diphtheria Immunization**—The Pittsburgh department of health in an investigation of diphtheria immunization recently found that, of 40,044 children investigated in 27,491 families, 7,679 had been immunized. Of the number of immunizations, 67.9 per cent had been done by public health agencies and 32.1 per cent by private physicians.

**Seminars at Sayre**—A series of six graduate seminars is being presented at Robert Packer Hospital, Sayre, under the auspices of the medical societies of Bradford, Sullivan, Susquehanna, Tioga and Wyoming counties. During June speakers were Drs Edward J G Beardsley, on cardiovascular renal disease, Edward L Bauer, diseases of children, Catharine MacFarlane, gynecologic conditions, and Vaughn C Garner, dermatologic subjects. All are from Philadelphia.

### Philadelphia

**Hospital News**—The Fridenberg Memorial Surgical Building of the Jewish Hospital was dedicated June 24. Judge Harry S McDevitt delivered the principal address. The building was erected at a cost of \$400,000 from a legacy left by the late Mone Samuel Fridenberg. It is five stories high and will accommodate 100 ward patients with no provisions for private or semiprivate patients.

**Memorial to Dr Knowles Proposed**—The Philadelphia County Medical Society is sponsoring a memorial fund to the late Dr George A Knowles, former assistant director of health of Philadelphia. Part of the fund will be used to have a bust made of Dr Knowles, to be mounted in the society's headquarters, and the remainder to create an endowment fund in the aid association of the society.

**Personal**—The University of Pennsylvania conferred the honorary degree of doctor of science on Dr William Gibson Spiller, emeritus professor of neurology in the school of medicine.—The honorary degree of doctor of science was conferred on Dr Robert F Ridpath, professor of rhinology, Temple University School of Medicine by Ursinus College, Collegeville, June 11.—Dr Horatio C Wood Jr received the honorary degree of master of science at the annual commencement of the Philadelphia College of Pharmacy and Science.—Dr Walter G Elmer has been advanced to professor of orthopedics at the Woman's Medical College of Pennsylvania.

### TENNESSEE

**University News**—Dr Marcus Pinson Neal, Columbia, Mo., is visiting professor of pathology and bacteriology at the University of Tennessee School of Medicine, Memphis during the summer quarter in the absence of Dr Harry C Schmeisser.—The annual Alpha Omega Alpha Lecture at Vanderbilt University School of Medicine was delivered, April 30, by Dr Samuel C Harvey, New Haven, Conn., on "Tumors of the Nervous System Derived from the Neural Crest."

**Health at Memphis**—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million indicate that the highest mortality rate (194) appears for Memphis and the rate for the group of cities as a whole was 10.8. The mortality rate for Memphis for the corresponding week of 1933 was 13.4 and for the group of cities, 10.2. The annual rate for eighty-six cities for the twenty-six weeks of 1934 was 12.1 as against a rate

of 115 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for wide areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

### UTAH

**State Medical Election**—At the fortieth annual session of the Utah State Medical Association, held in conjunction with the thirteenth annual meeting of the Pacific Northwest Medical Association at Salt Lake City, June 21-23, officers were chosen as follows: Drs. William R. Tyndale, Salt Lake City, president elect; Menzies J. MacFarlane, Cedar City, and Farley G. Eskelson, Vernal, vice presidents; and George N. Curtis, secretary. Dr. John Driver, Ogden, was made honorary president, the first physician to have this distinction, he is 85 years old. The next annual session will be held in Logan.

### VIRGINIA

**Dr. Riggins Appointed State Health Officer**—Dr. Warren F. Draper, assistant surgeon general of the U. S. Public Health Service, who has served as health officer of Virginia for the past three years, has resigned and will be succeeded by Dr. Irl C. Riggins, director of rural health work. Dr. Riggins, a graduate of Johns Hopkins University School of Medicine, Baltimore, was state epidemiologist for Virginia in 1925 and also served as health commissioner of Lorain County. Later he was executive director of the American Heart Association for several years, returning to Virginia as director of rural health work in July 1932. Dr. Draper, who has been on leave of absence, will return to the federal health service.

### WASHINGTON

**Personal**—Dr. Edward C. Ruge has resigned as superintendent of the Northern State Hospital at Sedro-Woolley. Dr. Howard L. Hull, superintendent and medical director of Oakhurst Sanatorium, Elma, since 1923, has resigned to enter private practice in Yakima. Dr. Leslie P. Anderson, White Haven, Pa., will succeed him. Dr. Max Cutler, Chicago, addressed the King County Medical Society, June 29, on pathology and treatment of neoplastic diseases.

### WEST VIRGINIA

**Society News**—Drs. Russell B. Bailey, Wheeling, and Earl Bannette Henson, Charleston, addressed the Raleigh County Medical Society, Beckley, June 7, on "Lesions of the Lungs and Mediastinum" and "Treatment of the Tuberculous Bone Lesion," respectively. Drs. Oscar H. Fulcher and Harry T. Schiefelbein, Welch, addressed the Mercer County Medical Society in a joint meeting with the McDowell County Medical Society at Bluefield, June 21, on "Presacral Sympathectomy for Bladder Conditions" and "Crossed Eyes," respectively. Dr. Richard B. Easley, Huntington, presented a paper on "Cisterna Magna Puncture: Its Technique and Use" before the Cabell County Medical Society, June 14. A symposium on heart disease was presented at a meeting of the Kanawha Medical Society, June 19, by Drs. George H. Barksdale and Pat A. Tuckwiller, Charleston. Drs. Martin L. Bonar, Charleston, and Clint W. Stallard, Montgomery, addressed the Fayette County Medical Society, Oak Hill, June 12, on "The Eczemas" and "Diagnosis of Sacro-Iliac Relaxation with Operative Treatment," respectively. Dr. William C. D. McCuskey, Wheeling, spoke on transurethral resection of the prostate at the final meeting of the Lewis County Medical Society for this season at Weston, June 7.

### WYOMING

**State Medical Meeting at Casper**—The thirty-first annual meeting of the Wyoming State Medical Society will be held in Casper, July 16-17, at the Elks Club under the presidency of Dr. Frederick L. Beck, Cheyenne. Guest speakers will include:

Dr. Adolph Sachs, Omaha, Modern Cardiac Therapy  
Dr. John Jay Keegan, Omaha, Emergency Brain Surgery  
Dr. Douglas W. Macomber, Denver, Early Diagnosis of Ectopic Pregnancy  
Gordon E. Davis, U. S. Public Health Service, Hamilton, Mont., Colorado Tick Fever

Wyoming physicians who will participate include:

Dr. Paul S. Read, Worland, Medical Economics  
Dr. Hugo L. Lucie, Cheyenne, Common Causes of Blindness  
Dr. Edwin Earl Whedon, Sheridan, The Spencer Parker Vaccine and Its Use in Sheridan County

The Natrona County Medical Society will entertain with a smoker Sunday evening, July 15, at the Gladstone Hotel, and a golf tournament will be begun Monday morning and finished Tuesday. There will be clinics at the county hospital Monday and Tuesday mornings and Dr. Nolie Mumey, Denver, will have a special exhibit of wax models of pathologic specimens.

### GENERAL

**Otolaryngology Examinations**—Sixty-two candidates were examined by the American Board of Otolaryngology in Cleveland, June 11, fourteen were conditioned or failed. Examinations will be held during the meeting of the American Academy of Ophthalmology and Otolaryngology in Chicago, September 8, and at the meeting of the Southern Medical Association in San Antonio, Texas, November 16. Prospective applicants for certificates should address the secretary, Dr. William P. Wherry, 1500 Medical Arts Building, Omaha, for application blanks.

**School Physicians' Meeting**—Dr. Charles H. Keene, Buffalo, was elected president of the American Association of School Physicians at its annual meeting at Saratoga Springs, June 27. Drs. John Sundvall, Ann Arbor, Mich., James F. Rogers, Washington, D. C., Charles C. Wilson, Evansville, Ind., and Haven Emerson, New York, were elected vice presidents and Dr. William A. Howe, New York State Department of Education, Albany, was named secretary. Among speakers on the program were the following:

Dr. William H. Park, New York, Immunization  
Dr. Edward Francis, Washington, D. C., Diagnosis of Undulant Fever  
Dr. Esmond R. Long, Philadelphia, Tuberculin: Proposal of a Standard Substance for Uniformity in Diagnosis and Epidemiology  
Dr. Simon Flexner, New York, Two Decades of Medical Research  
Dr. Hugh S. Cumming, Washington, D. C., Public Health in the United States  
Clarence C. Little, Seaside, Bar Harbor, Maine, Public Health Aspects of the Cancer Problem  
Dr. Henry D. Chadwick, Newton, Mass., School Health Service in Massachusetts

**Society News**—Dr. Thomas F. Abercrombie, Atlanta, Ga., was elected president and Dr. Alphonse Lessard, Quebec, Canada, vice president of the Conference of State and Provincial Health Authorities of North America at the annual meeting in Washington, D. C., June 6. Dr. Albert J. Chesley, St. Paul, was reelected secretary. The conference adopted a resolution expressing the opinion that a health officer or any physician connected with a health department should not allow his name or influence to be used in promoting the sale of any drug, remedy or proprietary food product. The western section of the American Congress of Physical Therapy, the Pacific Physical Therapy Association and the Los Angeles County Medical Association sponsored a postgraduate seminar on physical therapy at the Mayfair Hotel, Los Angeles, June 21, in which guest speakers were Drs. Disraeli W. Kobak, Chicago, on "Electrophysiology," "Present Status of Ultra-violet Therapy" and "Evaluation and Technique of Various Methods of Producing Artificial Fever," and Bernard L. Wyatt, Tucson, Ariz., "Newer Aspects in Treatment of Arthritis." The thirteenth annual scientific and clinical session of the American Congress of Physical Therapy will be held in Philadelphia, September 10-13.

### FOREIGN

**Madame Curie Dies**—Mme. Marie Sklodowska Curie, co-discoverer with her husband of radium, died of pernicious anemia at a sanatorium near Sallanches, France, July 4, aged 66. It was said that her long exposure to radiation probably hastened her death. Madame Curie was born in Warsaw, Poland, Nov. 7, 1867, and received her early scientific training under her father. After taking a degree in science at the University of Paris, she was married in 1895 to Prof. Pierre Curie. They began research on radioactivity in 1896 immediately after the property had been discovered in uranium by Becquerel. In 1898 they isolated radium from pitchblende. The Royal Society of England awarded the Curies the Davy medal in 1903, and the same year the Nobel prize in physics was awarded to them jointly with Becquerel. The French Academy of Sciences had previously honored them with the Lavoisier prize of 10,000 francs. In 1906 Professor Curie was killed in an accident and Madame Curie succeeded him as professor of physics at the university, the first woman to hold such a position there. In 1911 she received the Nobel prize in chemistry in recognition of her research. The University of Paris later created the Radium Institute and placed Madame Curie at the head of the research department, known as the Curie Laboratory, which she directed actively until a few weeks before her death. During the World War, Madame Curie

organized a radiologic service for treatment of wounded at the front. The distinguished scientist twice visited the United States. In 1921 she came to receive a gram of radium, valued at \$100,000, presented to her by President Harding on behalf of American citizens, in 1929 she returned to accept a check for \$50,000, presented for her friends by President Hoover in a ceremony at the National Academy of Sciences. The latter fund she gave to her native city of Warsaw for promotion of research on radium. In 1922 the Academy of Medicine in Paris elected her a member and the following year the French government voted her a pension of 40,000 francs a year. It was said that she lived humbly in Paris, using her income for the rental of radium. Among honors conferred on Madame Curie in recent years were the Cameron Prize of the University of Edinburgh and a gold medal conferred by the International Congress of Radiology at its Paris meeting, an honorary membership in the Sociedad Española de Física y Química, all in 1931.

## Government Services

### Trade Commission Charges Misrepresentation in Bayer Aspirin Advertising

The Federal Trade Commission has filed a complaint charging misrepresentation in connection with the sale of acetylsalicylic acid tablets against the Bayer Company, Inc. New York. The commission alleges that the company's advertising tends to mislead buyers into believing that 'Bayer aspirin' is the only genuine acetylsalicylic acid, intimating that the product sold by its competitors is not aspirin, is not as beneficial as the Bayer product, and is counterfeit or spurious. According to the complaint, Bayer advertising has proclaimed that its tablets will quickly relieve any and every pain and that any user may safely take as many tablets as necessary to relieve pain or to cure disease or sleeplessness. Relying on medical opinion, the commission stated that there are persons who cannot take such tablets safely even in small or moderate doses, others who cannot take more than the usual or prescribed dose and others to whom excessive use would be dangerous and even fatal. The commission pointed out that at most acetylsalicylic acid may be used to relieve pain resulting from the ailments mentioned in the company's advertising, but it is not adequate treatment for the underlying pathologic condition and will not relieve check, remove or cure it. The commission recounts the fact that acetylsalicylic acid was first imported into the United States from Germany in 1899, when the name "aspirin" was registered as a trademark. A United States patent was obtained in 1900 and the product was first sold in powdered form to druggists, physicians and manufacturing chemists but to the public only on prescription. About 1904 the German company authorized chemists to prepare it in tablet form, but, according to the commission's complaint, "in no case did the name of the respondent or its predecessor appear upon the containers." The chemists sold it under their own names, it was said. Bayer first sold the tablets to the public in 1915 but in 1917 the patent expired and the right to use the name "aspirin" became free to all. In 1918 the patent office canceled the trademark registered in 1899.

### Examinations for Appointment to Army Medical Corps

The War Department announces that examinations will be held September 24-28 for candidates who wish to qualify for appointment in the U. S. Army Medical Corps. General requirements for eligibility for appointment are that the candidate must be a male citizen of the United States between the ages of 23 and 32, must be a graduate of an acceptable medical school, must have a commission in the Medical Reserve Corps and must be physically fit. Candidates must also have had at least one year's hospital training subsequent to the completion of four years' instruction in a medical school or its equivalent in professional experience. The Medical Department has experienced an unusually large number of separations from the service during the past few months and the list of qualified candidates on the examinations held in March has been exhausted. Appointees from the forthcoming examinations will be ordered to the Medical Field Service School, Carlisle Barracks, Pa., for the basic course of instruction Jan. 1, 1935. Applications for authority to take the examination should be forwarded to the Adjutant General War Department Washington, D. C.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

June 16, 1934

### Voluntary and Municipal Hospitals

The great development in recent years of municipal (tax-supported) hospitals has been described previously. At a conference of voluntary hospitals in London, Sir George Newman, chief medical officer of the Ministry of Health, read a paper on Cooperation Between Voluntary and Municipal Hospitals. Referring to hospital accommodation in England and Wales, he said that there were about 1,850 hospitals with 215,000 beds consisting of 860 municipal hospitals with 143,000 beds provided by local authorities and about 1,000 voluntary hospitals with 72,000 beds. These totals included 130 hospitals and sanatoriums for tuberculosis provided by local authorities and 135 voluntary hospitals with 9,000 beds for tuberculosis. In addition to these totals the local authorities provided 172 hospitals with 139,000 beds for lunacy and mental deficiency and 1,310 hospitals with 194,000 beds for infectious diseases. Would it be wise to put all hospitals on a municipal basis of rates and taxes and allow the voluntary hospitals to disappear or would it be better to combine the two into one cooperative system? He strongly favored the latter. It would be more economical in the long run. There was now a legal obligation on the local authorities for cooperation with the voluntary hospitals, but in some areas this was not effective. Further organization was necessary for this purpose. Health officers reported that the desire for cooperation was widespread but that there was some indication of fear on the part of the representatives of voluntary hospitals that local authorities intended to compete unduly with these. A cooperative system of hospitals was likely, if properly organized, to be more economical in the long run than a tax-aided state system without the voluntary element, and it provided for their peculiar English genius for practical compromise between collectivism and individualism. It was satisfactory that forty-six county councils and sixty-eight county boroughs had already provided the means of mutual cooperation. In the discussion that followed Lord Riddell pointed out that the London Voluntary Hospitals Committee had done a great deal of useful work and established friendly relations with the county council, which controls the vast municipal hospital system of London.

### The Prevention of Accidents in Mines

In the house of commons the labor party tried to blame the government for accidents in mines. Between 1928 and 1932 there were 277 fire-damp explosions, causing the deaths of 315 men and injuring 538. It was asserted that these explosions were due to imperfect ventilation and violation of the regulations. The mines act provides that miners should be withdrawn when more than 25 per cent of gas is present but a labor member alleged that he had worked for hundreds of hours in the pit with 5 per cent of gas. Mr. Brown, secretary of the mines department, replied that there was no infallible cure for explosions in mines. The deaths over the last sixty years showed a large and progressive reduction. In the decade 1873-1882 the annual average was 65 per hundred thousand employed but in the decade 1923-1932 only 6. In the latter decade the average number of persons killed annually by explosions was 52 and the average killed underground from all causes was 933. The deaths from explosions were thus 5.5 per cent of the total deaths underground. In regard to nonfatal accidents the annual average from explosions was 100, of which some were slight, and from all causes underground 150,000. In the last hundred years no subject had received greater care and

thought or had more research done on it or had received more attention at the hands of those responsible for administering the law than the question of explosions. A big reduction in the number of deaths had taken place, mainly from the application of stone dust in the mines. He could not agree with the statement that if there was enough ventilation there would be no explosions. In the opinion of his advisers there were times and circumstances when it was impossible to prevent an accumulation of gas. In a period of ten years there had been 132 deaths and 154 injuries from shots fired. The number of explosions causing injuries, however slight, was forty-seven, but the number of shots fired in mines where there could have been explosions was some 300,000,000. Research work had resulted in many improvements to reduce the number of accidents. Some explosions occurred from natural causes, others from lack of proper ventilation or from bad distribution of air. There was always the problem of human fallibility. In that connection he might point out that between 1924 and 1933 there had been forty-seven deaths and fifty-nine cases of injury due directly to smoking and the presence of matches in mines. A labor member refused to accept these figures, but Mr. Brown felt bound to accept them, as they came from his advisers. He also insisted that the inspection of mines was adequate. The Safety in Mines Research Board was working actively not only in carrying out research but in preparing technical papers for technicians. Attention was being given to protective equipment to avoid the large number of accidents to hands, eyes, feet and heads, and experiments were being made with special types of gloves, goggles, boots and hats. A motion for the reduction of the vote for \$1,000,000 for the salaries and expenses of the Mines Department (the usual mode of censure) was rejected.

#### Conditions Under Which Advice on Birth Control May Be Given at Public Clinics

The question of giving advice on birth control at clinics provided under the public health acts has given rise to controversy. Three years ago the Ministry of Health issued a memorandum stating that certain clinics "will be available only for women who are in need of medical advice and treatment for gynecological conditions, and that advice on contraceptive methods will be given only to married women who attend the clinics for such medical advice or treatment, and in whose case pregnancy would be detrimental to health." In 1932 the departmental committee on maternal mortality and morbidity published its final report, in which it emphasized the importance of the avoidance of pregnancy by women suffering from organic disease, such as tuberculosis, heart disease, diabetes and chronic nephritis, in which child bearing is likely seriously to endanger life. The committee considered that advice on contraceptive methods should be readily available for such women. The Ministry of Health has now issued a circular to the effect that this advice shall be available to married women suffering from sickness, physical or mental, which is detrimental to them as mothers or renders pregnancy detrimental. The decision as to what is detrimental to health is to rest with the physician in charge of the clinic.

#### Checking Illicit Drug Traffic

The advisory committee of the League of Nations on opium and other narcotics has adopted a revised text of a narcotics convention, asking governments to provide legislation for severer treatment of drug traffickers and dealing with the "master mind behind the traffic which is often to be found in a country other than that in which the trafficking is taking place. The drug situation is now as follows. On the one hand the progressive shrinking in the volume of legitimate trade in opium coca leaves and manufactured drugs still continues. On the other hand supplies for illicit traffic in

manufactured drugs are more and more being drawn from clandestine manufacture, which continues to increase. The committee is pursuing the twofold objective of confining production and manufacture to the amount required for legitimate needs and to ensuring, through the strict application of the conventions, that the amounts so produced and manufactured in the legitimate trade do not escape into illicit traffic. It is also combating, with all the means at its disposal, the illicit traffic. As supplies are becoming more and more drawn from clandestine sources, the task becomes more difficult.

#### Changes in Symptoms of Acrodynia

Mr. Pehu of Lyons gave recently a discussion of acrodynia before the Academy of Medicine. He raised the question whether acrodynia today does not present different symptoms from the disease as observed last century. In 1828 the disorder took almost the form of a pandemic. It appeared suddenly and disappeared after a few months. The disease showed no predilection for children and it seems to have been contagious. Acrodynia, as known today, has continued for more than thirty years. It is not epidemic, is but slightly contagious, and affects chiefly children from 1½ to 5 years of age. There is, then, a resemblance between the two disorders but not a complete identity. During an interval of eighty years, the disease has undergone a number of changes. In support of his contention, Pehu gave detailed observations on the focus of acrodynia in the department of Saône-et-Loire, where forty-six cases were diagnosed from January 1925 to March 1934. The disease appears to be confined to the northeast part of the department. The cases almost always develop singly in each locality, although they are but a short distance apart. One cannot, however, speak of contagion proper. The annual number of cases ranges between three and five, with two maximums in 1930 and 1934 respectively. The cases occurred chiefly in children from 2 to 3 years old (twenty-one cases out of forty-six), no cases have been observed in adults or in children under 13 months. The symptoms are about as usual, although the evolution is long, extending over several months. The mortality is 10 per cent and results mainly from complications. Poliomyelitis is frequent in the same region. A more complete knowledge of this peculiar disease would be obtained if the practitioners who encounter it would make detailed observations.

#### Frequency of Tuberculosis in the Sexes

Prof. Leon Bernard and Mr. G. Poix have published a statistical research that reveals that tuberculosis in France, as in most countries, is more frequent in men than in women. The ratio is not the same at all ages, and one observes some differences from foreign countries. In France the mortality in females is higher than in males between the ages 5 and 25, after which it drops in females below that in males. In Switzerland, Italy and the Scandinavian countries, the mortality is higher in women than in men, whatever the age. After age 25, for each hundred deaths in males the number of deaths in females ranges from 73 to 79. After age 30, the excess of deaths in males becomes more marked. The inequalities in the mortality of the sexes is due to various factors but particularly to the work of women in factories. The greater frequency of tuberculosis in males explains why more requests for admission to sanatoriums are received from men than from women. These observations have a practical slant in the organization of the crusade against tuberculosis. In France there are only 9,393 sanatorium beds reserved for tuberculous men as against 10,404 beds for women, whereas the proportion should be just the reverse. Bernard concludes that it is time to reorganize

the tuberculosis services throughout the country. He urges the public authorities to take more accurate account of the real needs of the situation when they create new sanatoriums or render financial aid to them. In other words, a more rational and methodical plan should be adopted.

#### Foreign Mental Patients in France

The minister of public health has published a report on the number of foreign mental patients being cared for at present in France in the psychopathic hospitals, at the expense of the community or the government. The number cared for by virtue of reciprocity treaties with certain foreign countries is 1,435 out of a total of 3,250, or a little less than one half (Italians, 476, Poles, 605, Belgians, 117, Swiss, 27, Luxemburgers, 24, Spaniards, 107, Yugoslavs, 19, Austrians, 8, Hungarians, 6, Netherlands, 15, Norwegians, 18, Swedes, 4, citizens of the principality of Monaco, 2, and Greeks, 15). The other foreigners cannot claim the right to treatment other than on the basis of their own resources but they are usually admitted for reasons of humanity or because the cost of exportation would be greater than the cost of treatment. The tendency of large countries is to refuse admission to foreign mental patients in their territory and to accept only their nationals if the country from which they have come will take charge of their repatriation. This is a manifest abuse of privileges, which is harmful to France, which of all countries has the most foreigners in its territory, among which there are many who are rejected by their own country.

#### BERLIN

(From Our Regular Correspondent)

May 21, 1934

#### The Congress of Internal Medicine

The Deutsche Gesellschaft für innere Medizin held its annual session in Wiesbaden, April 9-12. Chairman Schittenhelm of Kiel emphasized that the society would serve the nation best if it would bring its investigations and its activities into harmony with the ideals of the new state. The training of the coming generation imposes new tasks in which the universities will play a more important part than they have in the past.

#### A DISCUSSION OF HEREDITY

Eugen Fischer of Berlin presented a paper on "Modern Theories of Heredity and Their Application to Man." It may be stated that the new mendelism, which has been found valid for many animal species, must be accepted also for man. In 1910 through research it was established that the chromosomes contain the fundamental principle that lies at the basis of hereditary transmission. The hereditary qualities are not fixed to a single pair of genes but to several pairs placed one after another in the form of a series. The theories pertaining to heredity in man rest today, in many respects, on a firmer basis than many other terms used in medicine for example, the theory of hormones. The theories with regard to heredity throw light on many pathologic questions and open up many diagnostic possibilities. Race research is still undergoing many rapid changes. Conceptions that formerly were regarded constant are now considered variable. It is regarded today as highly probable that the hormones are influenced by the genes, in which connection a distinction is made between genes easily changed and those changed with difficulty. Fischer thinks that racial differences have been brought about by mutations. Since physical qualities have not been found to be reliable as racial characteristics, Fischer is inclined to attach more importance to psychic qualities. Such problems show the need of a race psychology. The first step would be to create a race psychiatry. Taken in the most general sense, disease and the transmission of racial characteristics have nothing in common. The high incidence of some diseases in certain races might be due to

close inbreeding, but a marked tendency of a race toward the development of certain mutations may be in evidence. Fischer regards it as certain that the mental capacity and performance of the races vary to a certain extent. The specific culture of a people depends obviously on the racial qualities of its individual members. The physician must be thoroughly familiar with matters of heredity in order to be able to counsel patients with regard to propagation. He must be a judge with respect to hereditary pathology in particular in order to take a just stand toward the new law pertaining to sterilization.

Von Verschuer of Dahlem discussed the pathology of heredity. The gene (aside from the blood groups) is disturbed by environmental influence and by other genes. The best method for the delimitation of environment and hereditary characteristics and aptitudes is research on twins. Since enzygotic twins show a far reaching agreement in their hereditary qualities, diverse qualities in them must be due primarily to environment. But sometimes even in enzygotic twins an apparent disagreement is manifest, for example, owing to a more or less wide interval between the appearance of pathologic symptoms in the one twin and in the other (for instance, in tuberculosis), or owing to the fact that the symptoms are more marked in one twin than in the other. Frequently in schizophrenia the more intelligent twin exhibits graver symptoms. A hereditary quality is conditioned by the principal gene and the secondary genes. A secondary gene may, however, be the principal gene for some other characteristic.

For the necessary clarification of these problems, all opportunities for the securing of statistical material must be used. Bureaus of hereditary hygiene and clinics dealing with heredity are needed. Thorough research on whole racial groups must be carried out. Otto Nageli of Zurich presented the clinician's attitude toward the subject, dealing with the hereditary pathology of internal and nervous diseases. He discussed the question as to the hereditary transmission of acquired characters. All hereditary diseases are intimately associated with changes in the genes, which, it seems, can be brought about only by mutations. No proof has been adduced that acquired characters are susceptible to hereditary transmission. Further research will doubtless increase the number of hereditary changes and of hereditary diseases in man up into the thousands. Man as a new creation on earth is still passing through a mutation phase, in which new genes frequently appear. These hereditary factors may constitute unimportant variants, or they may become of great significance in the central nervous system. On the other hand, there is no fundamental difference between abnormality and disease, for example, in diseases of the blood. Under this head may be mentioned the carriers of certain hereditary diseases, who themselves, while not manifestly ill, are frequently not entirely normal, for example, women who transmit hemophilia but who themselves have slight disturbances of coagulation. The conception of genotypical variants as evidence of degeneration must be categorically denied. The term "degeneration" has a wide range of meaning and is frequently used in an absolutely erroneous manner, which then leads to false conclusions.

Dr. W. Gross of Berlin, the director of the Aufklärungsamt für Bevölkerungspolitik und Rassenpflege, discussed "Hereditary Biology in Relation to World Views of the National Socialists." He mentioned that it was the first time that political problems had been brought into the discussion at this congress, usually given to consideration of purely scientific questions. It is the task of political leaders to map out the routes and objectives, whereas it is the task of science to furnish to political leadership the equipment for laying the substructure. But it can never be the task of science to form world views in the wider sense and to exert a controlling influence over the mental attitude of a whole people. The impulses that have been

set forth by science during the past fourteen years have not had a favorable influence on the world views of the German people

Weitz of Stuttgart brought out the frequent occurrence of acquired cardiac defects in certain families. Evidence of pathologic hereditary trends may be found in vasoneurotic persons. Varices and status varicosus (telangiectasia and the like) often give evidence of dominant hereditary transmission, some renal disorders may be hereditary, for example, cystic kidneys. In pulmonary tuberculosis it is difficult to distinguish between hereditary and exogenous influences.

Luxemburger of Munich said that psychiatric hereditary research constitutes a special field of investigation, the fundamental basis of which is formed by studies on hereditary prognosis. The difficulty lies in the fact that in most hereditary psychic defects there is no evidence of a dominant hereditary transmission. The disorders in this field that are most important from the standpoint of heredity, such as schizophrenia, manic depressive insanity and epilepsy, follow the laws of recessive hereditary transmission, so that not only the actual patients but also healthy persons who present a latent predisposition must be excluded from hereditary succession. The first important question is the detection of the probable hereditary carriers, the second is the early recognition of the pathologic condition and the elaboration of the prepsychotic type.

With the aid of numerous family trees, Hanhart of Zurich demonstrated the hereditary transmission of predisposition to idiosyncrasies with a special reference to bronchial asthma. The hereditary factor is the increased sensitization, the result of certain allergens. The hereditary process is of the dominant type, but sex fixedness cannot be demonstrated. Likewise migraine is a common manifestation in persons with hereditary idiosyncrasies.

With reference to pathologic hereditary units, there is a dangerous tendency to apply mendelian laws, since the hereditary units of man have not yet been adequately studied. Attempts at elucidation must be kept within bounds and not anticipate progress of knowledge. More research is needed as a basis for more definite conclusions. Further communications brought out that hereditary predisposition to diabetes is causally connected with the genotype. There are hereditary thrombotic conditions which can be more closely delimited by the functioning of the blood platelets. With respect to myotonia congenita, the hereditary process was followed in one family through seven generations, with evidence of dominant hereditary transmission.

#### LOCALIZATION PRINCIPLE IN THE NERVOUS SYSTEM

The second topic, "The Significance and Scope of the Localization Principle in the Nervous System," was presented by Forster of Breslau. He emphasized that one can make an exact topical diagnosis solely with clinical methods, iodized poppy-seed oil and roentgenograms may sometimes deceive. In the discussion, Tonnies and H. R. Muller of Wurzburg stated that a differential diagnosis in brain tumors can be made in two thirds of the cases, and in a further 20 per cent by means of roentgen rays. In fact Tonnies was able with the aid of encephalography and arteriography, to reach a diagnosis in 95 per cent of the cases, confirmed through later operations.

Papers on the problems of circulation followed. Jacobi of Bonn pointed out that patients with heart defects and decompensated circulation are highly sensitive to pneumothorax, whereas compensated patients react the same as healthy persons. Bruns of Königsberg discussed the influence of respiratory disturbances on the lungs and the circulation. Oehme of Heidelberg reported that his experiment with irradiation of the hypophysis in exophthalmic goiter proved unsuccessful. The paper by Butenandt of Danzig concerned "The Physiology and Chemistry of the Sex Hormones." The subdivision of the

gonadotropic effective principle into two different substances has not been experimentally proved. The gonadotropic hormones, as Aschheim and Zondek have found, are present in abundance in the urine of gravidæ, they are biologically identical with the hormone of the prchypophysis, but they take their origin from the placenta. Gonadotropic substance is not present in the hypophysis of the pregnant woman. The chemical composition of the gonadotropic hormones is not yet known. The testicular hormone is excreted in the male urine, Butenandt isolated it therefrom in a crystallized condition in 1931. Also the follicular hormone has been isolated in a crystal form. It is demonstrable in the blood and the urine of the sexually mature woman, in the placenta, in the urine of sexually mature stallions, and even in bituminous substances, but the corpus luteum hormone has been found thus far only in the corpus luteum. The follicular hormone promotes not only the growth of the genital tract but also, quite generally, the growth of plants. In pregnancy it brings about a loosening of the symphysis and a pigmentation of the linea alba. Furthermore, it effects a reconstruction of the uterine mucosa in the proliferative phase, whereas the corpus luteum hormone then launches the secretory phase of the uterine mucosa. The sex hormones function according to mutual laws, probably under the guidance of a special brain center. In a woman who had been subjected to bilateral ovariectomy, normal menstruation was effected by the administration of 250,000 mouse units of follicular hormone (1 million international units) and later of from 30 to 50 units of corpus luteum hormone.

R. Schroder of Kiel discussed "Normal and Pathologic Ovarian Function." Only disturbances of ovarian activity as such can be directly influenced by hormone therapy. For the treatment of disturbances due to muscular changes, other measures should be adopted. In menstruation occurring after three weeks, the corpus luteum phase is shortened, if the interval is prolonged, damage to the follicular function results. In connection with suppression of the menses, there is frequently an increased excretion of hormones, doubtless as the result of subliminal hormone production. Associated with persistence of the follicle, and likewise with long continued administration of the follicular hormone, one may observe hemorrhages, extending over several weeks, which have no connection with the menses. Concerning the quantity of hormones in the circulating blood, no definite statements can be made, likewise little is known about the qualitative changes occurring in the hormones. The corpus luteum hormone has been found effective in habitual abortion.

Siebek, a collaborator of Schroder, then discussed "The Therapeutic Uses of Sex Hormones." Unsuccessful results are due to false indications and incorrect dosage, and, to some extent, to the fact that one expects folliculin to accomplish what only the corpus luteum hormone can effect. In point of fact, often enormous quantities are indicated—much greater than are practical for the present.

According to Burger of Bonn, the chemical changes occurring in the human organism in old age are due to increasing loss of fluids and the resulting increase in the dry residues of the tissues—which may lead to the formation of precipitates and to nutritional difficulties.

Further communications dealt with diverticulosis of the intestines, the action of extract of the suprarenal cortex and the like. Professor Schottmüller of Hamburg was elected president for the ensuing year.

#### Twin Births in Germany

According to recent statistics, there were 13,248 twins in Germany, about half of them being in Prussia. The Palatinate has three survivors from a set of quintuplets, Rhineland and

Hesse have each one set of living quadruplets. The remaining multiple births are distributed rather evenly over the cities and rural districts. There appears to be no foundation for the assertion that multiple births occur more frequently in any one German tribe or in any particular class of the population.

## PRAGUE

(From Our Regular Correspondent)

June 2, 1934

### Congress of Dermatologists

The Congress of Slavic Dermatologists in Prague, May 19-21, was the third reunion of this organization, the first having been held in Belgrade and the second in Warsaw. The congress was presided over by Prof. F. Samberger of the university of Prague. It was organized by the Federation of Slavic Dermatologists, to which now belong national committees in Bulgaria, Czechoslovakia, Poland and Yugoslavia, the Russians being the only Slavic nation which has abstained from participation. The congress dealt with three topics. The first report presented observations on intradermal reactions presented by Dr. L. Popoff of Sofia. Tuberculosis of the skin was the second point of discussion. The third report, presented by Prof. R. Lesczinski of Lwow, dealt with the relationship of the reticulo-endothelial system to the skin. Besides the main topics, free lectures and some thirty other communications were presented. The organization is growing and is establishing slowly a reputable tradition. The kinship of the languages of the Slavic nations is a strong bond which facilitates enormously the exchange of scientific information among the Slavic physicians, who in spite of using their own language in their meetings make themselves understood.

### Dental Clinics

A national organization for the dental care of school children was organized in Czechoslovakia about a year ago. Systematic work on the protection of the teeth of school children was started in Prague in 1907 but remained limited to this city. Later other cities followed with the erection of dental clinics for school children, but there was no institution for central direction of this work. At present about forty dental clinics are functioning in connection with the work of the Junior Red Cross. It is estimated that about 150,000 school children obtain dental care in these clinics, which of course represents a small proportion of the 2,000,000 school children in the state. The main effort of the organization tends toward the foundation of new school dental clinics. In some places as many as 97 per cent of the school children have left the school with a perfect condition of the teeth. Experiments are also conducted with mobile dental clinics for children in rural territories. The program concerns prophylactic care, which is mainly educational, and the nutrition of the child. The rapid development of the organization in spite of the difficult times was made possible through the help of the Central Insurance Body.

### Birth Control

The Federation for Birth Control was recently founded in Prague. Some years ago this movement had only a few promoters. The propaganda for the legalization of abortion of the last few years visualized the amount of suffering that results from undesired pregnancies and made the public realize that there was a way to prevent it. The federation was organized mainly on the initiative of women's societies and the organizations of social workers. A deputation presented recently to the minister of health a memorandum in which the attention of the public authorities was called to the fact that the prevention of conception has become in Czechoslovakia a lucrative branch of quackery. The assistance of public authorities was solicited for educational propaganda against this

mischievous help was asked for the erection of consultation stations for mothers giving advice in all matters pertaining to matrimony. The first station of this kind was opened recently in Brno with the assistance of the Red Cross. The main difficulty that this type of work encounters is the resistance of the Catholic Church, to which belong the majority of the population. The Czechoslovakian Church declared itself ready to support consultation stations for the promotion of hygiene in matrimonial life provided they are conducted by medical specialists. The official organizations for child welfare stand aloof from the new organization, maintaining that the preservation of children's lives is their main concern.

### Increase in Number of Physicians

The rapid increase of physicians in Czechoslovakia is causing medical organizations to worry. Recently a comparison was brought to light between the number of physicians practicing in Czechoslovakia in 1930 and in 1933. It appears that there was an increase of 20 per cent of physicians within this time. The greatest increase could be observed among the dental surgeons. In 1930 there was one practicing physician to 2,046 inhabitants, in 1933 there was one to only 1,689. If the number of physicians continues to increase at the same rate there will be within about eight years one physician to 1,200 inhabitants, which is considered the limit at which physicians can make a living under the present conditions. The demand for the restriction of medical students is being expressed with a strong emphasis.

### Congress of Socialistic Physicians

An international congress of socialistic physicians was held in Brno, May 21, with representatives from London, Oslo, Budapest, Zurich, Copenhagen and Stockholm. There is a tendency among a number of physicians of Europe to organize themselves with political parties, including those with socialistic tendencies. Especially among the young physicians there can be observed a tendency to engage in political activities. Such a movement is noticeable in Czechoslovakia, and this country was selected for this international congress. The request of the communistic physicians to be admitted into this organization was refused by the congress. This group of physicians in Czechoslovakia has been able to found its own monthly periodical.

### Birthday of Weigner the Anatomist

The sixtieth birthday of Dr. Charles Weigner, professor of topographic anatomy, was celebrated recently. Professor Weigner is one of the dominant personalities of the Czech Medical Faculty of Prague. Under his teacher Prof. J. Janosik he began as a medical student his work on the anatomy of the nervous system, which he pursued for ten consecutive years. In 1901 he began lecturing at the faculty of medicine and was appointed professor in 1906. In 1918 he obtained the chair of topographic anatomy, and in 1928 he succeeded Professor Janosik as the head of the Anatomical Institute of the Charles University in Prague. He has written some 180 scientific papers. The most important part of his work deals with anatomy, which has a direct bearing on practical medicine, especially surgery. With Prof. L. Syllaba he pursued studies on the correlation of physical observations to morbid conditions of the internal organs. His further work was concerned with the topography of the brain and skull, especially with regard to brain surgery. He started early to write a handbook of topographic anatomy, which is in its second edition. He has a profound influence on the growing generation of the medical profession and he is among the most diligent and popular teachers. He has never confined his efforts to the medical faculty. He became the organizer of the movement for scientific direction of physical education. He organized courses for

teachers of physical education and grouped around himself the most important workers from this field. After the World War he played also a role for a time in politics. His work in popular education regarding the knowledge of the human body and of physical education is based on his conviction that modern science must not remain enclosed within the walls of the university but that its chief function is to provide service to the broadest masses of the population.

#### Biologist Dies

The founder of Czech medical biology, Prof. Vladislav Ruzicka, died recently in Prague, at the age of 64 years. His whole career was connected with the Czech medical faculty of Prague. He made fundamental observations on chromatin. According to him, the external conditions in which the ovum develops determine the constitution of the individual, which is the only feature that can be inherited. This constitution is a certain morphochemical structure of living matter which possesses the ability to reproduce this type of structure. World wide recognition was accorded to his theory of the causes of aging. Practically all his work after 1917 was concentrated on this problem. He recognized that in the course of life there proceeds a densification of living matter which can be demonstrated by physicochemical methods. He called the densification of colloids in the living matter hysteresis of the protoplasm, and this term was accepted by the biologists of the world. Although the center of Ruzicka's activity lay in laboratory work, he was at the same time a prominent teacher and organizer. He accomplished the erection of a new institute of medical biology in the medical faculty of Prague, of which he became the first chief. He organized also the Czechoslovak Eugenic Society, of which he was the first president. Owing to his activities, a number of eugenic stations were organized. His international reputation found its expression in the fact that with Pearl and Lohner he became the editor of the *International Archives of General Biology*. He was a member of the International Committee of Eugenics in London and, since 1930, vice president of the International Federation of Eugenic Organizations. In 1930 he served as a dean of the Medical Faculty of the Charles University of Prague. His pupils hold chairs of medical biology on all the Czech medical faculties of Czechoslovakia.

#### Restriction of Foreign Physicians

The question of foreigners trying to obtain permission to practice medicine in Czechoslovakia is becoming acute. After the war, emigration from Russia brought to Czechoslovakia many foreign students, later there was an influx of Jewish students from Poland, Rumania and Hungary. At present, only citizens who hold a medical diploma from a Czechoslovakian university have the right to practice in the country. It was thought that the lack of citizenship would prevent foreign students from establishing themselves for practice after graduation. Nevertheless in the course of their studies most of them became acquainted with local conditions, found access into Czechoslovakian families, and through their support obtained citizenship in many cases. This question has again attracted general interest as the new regime started in Germany. Many young emigrants, especially of Jewish origin, came to Prague asking for admission into the faculties of medicine. A recent meeting of all the chambers of physicians dealt with this problem and elaborated a memorandum addressed to the government. The document recommends that university authorities be strict in interpreting the preliminary qualifications of those who ask for registration. It favors the introduction of a clause in the diploma specifying that the graduate shall not be admitted to practice even if he obtains citizenship in Czechoslovakia.

## Marriages

DAVID KENNETH LEIBY, New Hope, Pa., to Miss Winifred Lawson Rainford of Philadelphia, June 29.

CHARLES EDWARD DOWMAN JR., Atlanta, Ga., to Dr. CORDELIA KOCH of Towson, Md., June 14.

AUBREY H. WILLIAMS, Fort Wayne, Ind., to Dr. A. BERNICE MORRIS of New Haven, June 12.

WILLIAM M. ROBINSON, Richmond, Va., to Miss Bluma Dolinsky of Chicago, May 27.

HERSCHEL STRATTON MURPHY to Miss Helen Moore, both of Roselle N. J., June 30.

## Deaths

Frederick C. Ainsworth, Major General, U. S. Army, retired, Washington, D. C., University of the City of New York Medical Department, 1874, entered the army as an assistant surgeon in 1874, promoted to major surgeon in 1891, colonel in 1892, brigadier general in 1899, major general in 1904 and the adjutant general in 1907, retired in 1912 at his own request after thirty years' service, aged 81, died, June 5, of bronchopneumonia and arteriosclerosis.

Frank Roy Morton, Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901, past president and secretary of the Chicago Medical Society, fellow of the American College of Surgeons, chief surgeon to the Standard Oil Company of Indiana, on the staff of the Henrotin Hospital, aged 53, died, June 16, in Joliet, Ill., of coronary thrombosis.

Carl John J. Holman, Los Angeles, Rush Medical College, Chicago, 1899, fellow of the American College of Surgeons, at one time member of the Minnesota State Board of Medical Examiners, one of the founders of the Mankato (Minn.) Clinic formerly on the staff of St. Joseph's Hospital, Mankato, an honorary member of the Blue Earth County (Minn.) Medical Society, aged 64, died, May 30.

Martin Van Buren Godbey, Charleston, W. Va., Maryland Medical College, Baltimore, 1905, fellow of the American College of Surgeons, member of the state board of health, 1909-1913, served during the World War, at one time member of the state legislature, formerly physician in charge of the McKendree (W. Va.) Hospital, No. 2, aged 54, died, April 26, of heart disease.

Charles Carroll Geer, First Lieut., U. S. Army, retired, Greenville, S. C., Bellevue Hospital Medical College, New York, 1895, veteran of the Spanish-American War, entered the regular army as an assistant surgeon in 1901 and retired in 1904 for disability in line of duty, aged 63, died, May 18, of cerebral hemorrhage and arteriosclerosis.

James Norman McCoy, Vincennes, Ind., University of Indianapolis Medical Department, 1896, member of the Indiana State Medical Association, member of the American Roentgen Ray Society, served during the World War, formerly secretary of the county board of health, aged 60, died suddenly, April 16, of angina pectoris.

Frederick Walker St. Clair, Indiana, Pa., University of Pittsburgh School of Medicine, 1913, member of the Associated Anesthetists of the United States and Canada, past president and secretary of the Indiana County Medical Society, county coroner, served during the World War, aged 48, died, June 6, of malignant endocarditis.

Francis Joseph Broghammer, Superior, Wis., Marquette University School of Medicine, Milwaukee, 1913, past president and secretary of the Douglas County Medical Society, served during the World War on the staff of St. Mary's Hospital, aged 45, died suddenly, May 29, of heart disease.

Kim Devol Curtis, Phoenix, Ariz., Baltimore Medical College, 1907, member of the Arizona State Medical Association, at one time on the staff of the State Hospital, No. 2, St. Joseph, Mo., aged 49, on the staff of the Arizona State Hospital where he died suddenly, June 1, of cerebral hemorrhage.

Ludwig Schoenthal, New York, Medizinische Fakultät der Universität Frankfurt-am-Main, Frankfurt-on-Main, Germany, 1923, associate in clinical pediatrics, Cornell University Medical College, associate attending pediatrician to the New York Hospital, aged 34, died, June 15, of staphylococcal septicemia.

Lester Hall Hummel, Salem, N J, Baltimore Medical College, 1897, member of the Medical Society of New Jersey, member of the board of education and board of health, on the staff of the Salem County Memorial Hospital, aged 61, died June 7, of myocarditis and cerebral hemorrhage

Theodore Breck, Brecksville, Ohio, Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1894, aged 66, died, June 13 in the Glenville Hospital, Cleveland, of complications following an operation for appendicitis

Walter B Foss & Ashley, Pa, College of Physicians and Surgeons, Baltimore, 1887, for many years bank president and member of the board of health of Ashley aged 74 died, May 6, in the Wilkes-Barre (Pa) General Hospital, following an operation

Paul Hays Fithian, Danville Ill, College of Physicians and Surgeons, Keokuk, Iowa, 1890 Rush Medical College, Chicago, 1891, member of the Illinois State Medical Society, aged 68, died, May 22, in Kankakee, of cerebral hemorrhage

John Otis Garfield Niles & Everett, Mass Harvard University Medical School, Boston, 1914 aged 54, died, June 5, presumably of heart disease, while swimming near his summer home on Plum Island

Emil Albert Ruka & Muscoda, Wis Rush Medical College, Chicago, 1915 served during the World War, aged 43 died, May 29, of internal hemorrhage caused by carrying a patient up the stairs

James Wilson Clements, Subigna, Ga Medical College of Virginia, Richmond, 1864, member of the Medical Association of Georgia, Confederate veteran, aged 94, died, June 5, of acute gastritis

Blanche Alpine Denig, Oakland, Calif Woman's Medical College, Chicago, 1891, member of the Massachusetts Medical Society, aged 72, died, May 21, of coronary occlusion and arteriosclerosis

Finley D Blackwell, Hochheim, Texas, Tulane University of Louisiana Medical Department, New Orleans 1898, aged 59, died, May 28, in a hospital at Cuero, of acute nephritis

John Henry Franklin & Guadalupe, Calif University of California Medical Department, San Francisco 1906, aged 54, died, April 24 in Santa Maria, of cardiorenal vascular disease

Julus Arthur Bullard, Montrose Pa Hahnemann Medical College of Philadelphia, 1872, aged 83, died, May 25, in Miami, Fla, of coronary thrombosis and arteriosclerosis

Henry Peter Hansen & Burns Wyo, Drake University College of Medicine, Des Moines, 1907, aged 48, died, April 28, of hemorrhage and hypertrophic biliary cirrhosis

James Hodgen Burkhead, Middleboro Mass, College of Physicians and Surgeons Baltimore, 1907, aged 53, died, May 13, of cholangitis and embolism

Ellsworth Martin Burke & Havre, Mont, University of Louisville (Ky) School of Medicine 1921, aged 42, died, May 28, of hypertensive heart disease

Jonathan Evans Clark, Ringgold Ga, Chattanooga (Tenn) Medical College, 1900, aged 84, died, May 9, near Boynton, of pernicious anemia

Victor Charles Doherty, Detroit, University of Michigan Medical School, Ann Arbor, 1898, aged 58, died suddenly, June 10, of coronary occlusion

William McGlasson Corey, Erlanger Ky Eclectic Medical Institute, Cincinnati, 1886, aged 68, died, May 29, of angina pectoris and arteriosclerosis

Orlando G Gibson, St Louis Homeopathic Medical College of Missouri, St Louis, 1897, aged 61, died suddenly, May 30, of heart disease

Ulysses Eugene Hartley & St Louis, St Louis University School of Medicine, 1918, aged 42, died, June 6 of poison, self-administered

Willard Fiske, Lancaster Texas, University of Tennessee Medical Department, Nashville, 1884, aged 83, died, May 19, of cerebral hemorrhage

William Spankie, Wolfe Island Ont Canada, Queen's University Faculty of Medicine, Kingston, 1885, aged 74, died, May 27, in Kingston

Henry A Denson, Bennett, N C Central College of Physicians and Surgeons, Indianapolis, 1887, aged 80, died, June 2, of uremia

Lonzo Abner Duck, Webster Groves, Mo St Louis College of Physicians and Surgeons 1903, aged 55 died May 18, of heart disease

### A METHOD FOR THE PRESERVATION OF CLEANLINESS ON PLASTER-OF-PARIS CASTS

*To the Editor*—Members of the profession who use to any extent plaster-of-paris casts universally find that sooner or later the plaster becomes soiled This is true especially with children, who during their activities ruin the clean appearance of the cast as it was originally applied Parents as well as the patients themselves are constantly asking to have a new cast or the old one cleaned in order to make a more presentable appearance Cleaning is, of course, practically impossible and one is loath to apply new casts

This problem was recently solved for me by a patient I have investigated the literature and have been unable to find the method described, although it is so simple that I would hardly feel fair in calling it original

A cast had been applied to this man's hand, wrist and forearm for the care of a fractured carpal scaphoid bone Shortly after the application he left for a month's vacation in Bermuda On his return he told me that in order to keep his cast presentable he had applied quick-drying white lacquer This left a glossy, smooth coating, which could be easily washed without injury to the cast Once, because of chipping of the paint, he applied a new coat

The simplicity of the procedure makes the method a valuable adjunct for the care of any cast It can be applied any time after the plaster is dry and should prove useful to any one doing fracture surgery

PAUL W GREELEY, M D, Winnetka, Ill

### PNEUMOTHORAX IN PNEUMONIA

*To the Editor*—A number of Eastern hospitals have lately reported experimentation with pneumothorax in pneumonia In 1915 and 1916 I had some correspondence with the late Dr John B Murphy when he was pioneering in the pneumothorax treatment of tuberculosis

I made the suggestion to him at that time that the same treatment be applied in early unilateral lobar pneumonia The following reasons were offered

First Rest to the involved lung

Second Relief of pleural pains, minus opiates Under date of April 15, 1916, Dr Murphy wrote me

I have referred it to my associate Dr Kreuscher who has charge of the pneumothorax department of my clinic I have given instructions that it be done as soon as possible and will be pleased to report to you Thanking you for the suggestion and with best wishes I am

Yours very truly,

J B MURPHY

In view of the fact that Dr Murphy died in August 1916, this work was not carried on as had been planned

THOMAS J WEST, M D, Pasadena, Calif

### STAPHYLOCOCCUS TOXOID IN PUSTULAR DERMATOSES

*To the Editor*—The communication from our Canadian colleague Dolman in THE JOURNAL, May 19, criticizing the report of Kindel and Costello on their observations of the effect of staphylococcus toxoid on pustular dermatoses is evidently based on a misunderstanding He fails to appreciate the background for the study and report of Kindel and Costello

Clinical departments in teaching institutions of medicine in the United States, as elsewhere, are continually being impounded by pharmaceutical manufacturers to try this or that

product recommended in various clinical conditions. The reason for this is self evident.

In Dr Howard Fox's department of dermatology in the New York University and Bellevue Hospital Medical School it has always been the policy to give drug manufacturers a respectful hearing and, when the representation warranted, to assign interested members of the staff to make short but properly controlled clinical studies to secure first hand knowledge in respect of the claims that are made. Dr Fox has rightly felt that teachers in medicine should be in the vanguard of those acquainted with newer methods in diagnosis and therapy and active participants in the controversial phase through which these newer things must of necessity pass.

Kindel and Costello's report is based on the use of a toxoid made by a single but reputable manufacturer of biologicals. Their deductions are sound. What Dr Dolman fails to appreciate is that Kindel and Costello are directing their charge of overenthusiasm not at our Canadian colleague but at the inarticulate many who have endorsed to this manufacturer the very product Kindel and Costello used.

HERMAN SHARLIT, M.D., New York

## Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

### TANNING OF SKIN

*To the Editor*—Please tell me what truth there is in such remarks as Vinegar dabbed on the skin before going out for a sunbath will hasten a quick tan and prevent peeling or Olive oil will do the same thing. Are there any substances which if applied before the patients sun themselves will hasten a tan or prevent peeling? Please omit name and address.

M.D. California

**ANSWER**—Vinegar evaporates in the sunlight and has no effect on tanning or peeling. Nonvolatile oil on the skin interferes to some extent with the absorption of light and therefore protects against sunburn and the subsequent peeling. Nothing will hasten tanning; it depends on the ability of the pigment-producing cells in the skin to react evenly to the stimulus of light. Most skins of dark complexion have this ability, but some blondes lack it and burn without subsequent tanning or freckle as a result of exposure to light. Such skins cannot be changed; they must be protected from strong sunlight in such reactions are to be avoided.

Tanning without the discomfort of sunburn or the inconvenience of peeling can be acquired only by careful dosing of sunlight, short exposures at first, gradually lengthened.

### POSSIBLE SENSITIZATION TO NAIL WHITE

*To the Editor*—A patient tells me that every time she uses Cutex nail white (a substance that is spread under the nails) she has a severe diarrhea lasting several days. Is the diarrhea caused by the nail white? Please omit name.

M.D. New York

**ANSWER**—No analysis of this product has been made by the laboratory of the American Medical Association and the manufacturer has not responded to a request for information regarding its constituents. The nail white is a suspension of an insoluble white powder in a highly perfumed volatile base. On application to the skin, the base evaporates promptly and leaves the powder adhering to the skin.

Assuming that the cosmetic preparation is really responsible for the attacks of diarrhea, two possibilities suggest themselves: that one or more of the constituents of the preparation are absorbed and produce a toxic effect or that the patient is hypersensitive to one or more of the constituents. A third possibility is that the patient is a malingerer who takes some cathartic at the time she uses the 'nail white' in the attempt to make a case against the manufacturers.

The first possibility is a far fetched one. If any of the ingredients of this preparation were so toxic, how could any one be found willing to make it?

The second is a real possibility. Sensitization to a degree sufficient to produce a prompt diarrhea is not hard to imagine. As the constituents of the preparation are not known, it is impossible to determine by skin tests or inhalation tests to just what substance the patient is sensitized. Tests can be made with the whole preparation but, in view of the third possibility, should be made in the hospital with the patient under the strict surveillance of a nurse trained in this sort of work. Hysterical patients, who constitute the majority of malingerers, are sly and can deceive most physicians and nurses.

The treatment of the case is easy. Let the patient be satisfied with soap and water cleansing. The water used in washing dishes and clothes is said to be particularly efficacious.

### GASTRIC LAVAGE

*To the Editor*—Please recommend adequate equipment for stomach washing at home in cases in which poison has been swallowed stating definitely the sizes of tubes to be used at different ages. What position is best for a small child undergoing this treatment? Please omit name.

M.D. New Jersey

**ANSWER**—A stomach tube, if it is available, or a soft rubber catheter may be used to wash the infant's or child's stomach. The catheter or tube is connected to one-fourth inch plain rubber tubing with a glass connecting tube. A funnel is inserted into the upper end of the tube. An additional opening may be cut into the catheter about half an inch above the original eye, or a tube may be used in which the lower end is entirely open. The catheter or stomach tube used for the washing should be the largest size that can be readily passed through the esophagus into the stomach. It has been suggested that the catheter selected should be about the size of the child's index finger. A French size 18 catheter or, in older children, one of size 20 to 26 on the French scale may be employed. The soft rubber stomach tubes 5 feet long may be obtained in the instrument shops, plain, with a funnel or with bulb and funnel attached, with the lower end open and an additional eye. These sizes vary from 22 to 32, French scale. It is obvious that the size of the catheter to be used depends on the weight and development of the infant or child; consequently the size of the tube required will vary in individual cases. When the lavage is to be performed, the child should be securely wrapped in a sheet so as to fasten the arms to the sides of the body. The child should be firmly held in the attendant's lap or may be placed on a table, lying on the side. In this position, with the help of one or two assistants, the patient may be held securely and the treatment completed.

### HYPERTENSION AT BIRTH—FETAL KIDNEY—CONGENITAL IMPERFORATE URETHRA—AMNIOTIC FLUID

*To the Editor*—A case of congenital polycystic kidneys in an infant aged 6 months with hypertension and the finding post mortem of marked hypertrophy and dilatation of the left side of the heart presented for discussion at a recent clinical pathologic conference has stimulated several questions to which I cannot seem to find satisfactory answers. 1. Has hypertension been found present at birth? 2. Do the fetal kidneys excrete urine during intra uterine life? 3. Are there cases of congenital imperforate urethra on record? If so, what are the pathologic changes in the kidney and the bladder? 4. What is the source of the amniotic fluid?

WILLIS P. BAKER, M.D. Santa Ana Calif

**ANSWER**—1. There is no available material to substantiate an opinion regarding hypertension at birth. It is present possibly in cases of congenital polycystic kidneys.

2. Almost all investigators agree that the fetal kidneys are capable of excreting urine, especially in the later months of pregnancy. Undoubtedly the waste matter of metabolism of the fetus is carried away by the fetal circulation to the placenta and then is absorbed into the maternal circulation and excreted through the maternal kidneys. Consequently there is no need for renal function in the fetus. The fact that a new born child will pass urine immediately after birth and the presence of casts in the urine at birth would denote renal activity. The presence of urine-like fluid in the cysts of polycystic kidneys at birth and the presence of hydronephrosis in cases of imperforate urethra also suggest renal activity of the fetus.

3. There are cases of congenital imperforate urethra on record. This condition may be associated with various conditions. There may be distention of the bladder and ureters and hydronephrosis. Urine may be discharged through the urachus or, in cases in which the urachus is not wholly patent, fluid may collect, forming single or multiple cysts of the urachus, which at times contain large quantities of urine. If the normal exit of the urine is obstructed the remnant of the urachal tube

may carry on the function of a urinary fistula. Occasionally, bladder diverticula have been observed in these cases. Ectrophy of the bladder may be an associated malformation. If, in the male, the imperforation is at the distal end the entire urethra may be dilated into a sac. Owing to the length and the relation to the internal generative organs, malformations are more frequently seen in the male urethra than in the female urethra.

4. Amniotic fluid is normally derived from the fluids of the mother that have been modified by the secretory action of the epithelial lining of the amnion. The fetal kidneys probably take little or no part in its production, under normal circumstances. Hydrannios is occasionally seen in cases of fetal abnormality, such as hemicephalus or spina bifida. In these conditions the excess fluid is thought to be a result of excessive urinary secretion due to stimulation of unprotected nerve centers. More frequently, hydrannios is associated with obstruction to circulation within the cord or the fetus. Histologic changes interpreted as manifestations of secretory activity have been observed in the amniotic epithelium. A great part of the amniotic fluid may represent a transudation through the surface of the fetus and the vessels. There is evidence to support the belief that a considerable amount of amniotic fluid is swallowed by the fetus and absorbed through the digestive tract.

#### NASAL AND PHARYNGEAL SECRETION IN TUBERCULOSIS

*To the Editor*—Will you kindly tell me why a patient with advanced tuberculosis but practically without active symptoms should have a deficiency of lacrimal and mucous membrane (nose and mouth) secretion. The patient is thin but takes an adequate amount of fluid and a general diet though not adequate for gain in weight. Few drugs are taken including acetylsalicylic acid an occasional cough sedative and dilute hydrochloric acid. At present small doses of insulin are being tried in an effort to improve the weight. The dryness of the mucous surfaces is so marked as to cause definite discomfort and this has extended over a long period of time. Will you suggest some measure that will improve the condition? Please omit name and address. M D Virginia

**ANSWER**—As a rule in tuberculosis there is no involvement of the lacrimal apparatus or of the secretion of the lacrimal gland of the nasal or the oral mucosa. It is possible, however, that the dryness of the mucous membrane is due to a marked anemia or to a dehydration of the individual from some cause other than tuberculosis. Careful blood examination is therefore advisable. Sometimes the use of slightly acidulated water, that is to say, water to which a few drops of lemon juice have been added, will often stimulate the flow of saliva and so relieve the dryness of the mouth. In the nose, the use of a few drops of a bland oil such as white liquid petrolatum is efficacious. At times, from three to five drops of saturated potassium iodide solution by mouth three times a day will increase the nasal and pharyngeal secretion.

#### TREATMENT OF GINGIVITIS

*To the Editor*—Can you suggest treatment for a case of refractory gingivitis in a boy of 3½? About a year ago swelling and ulceration of the gums with fever developed suddenly. A microscopic examination for Vincent's angina was negative. Another examination about two months ago was negative. The mother has used an assortment of local applications including mercurochrome boric acid hexylresorcinol S T 37 hydrogen dioxide and methylene blue prescribed by the attending physician and two dentists. The child was born by cesarean section and was bottle fed. His development has been normal and his diet has been well supervised. He is apparently quite normal in every way except that cod liver oil in any form and viosterol have always nauseated him. At present the lesions have caused recession of certain portions of the gum nearly to the roots of the teeth. At times there is almost complete healing and then the process flares up with no relation to the current medication. The tongue always has a light white coating. Citrus fruits and tomato juices now irritate the gums. About two years ago the father had all his teeth extracted for pyorrhea. He insists now as then in using his own and the baby's eating utensils interchangeably. Is it possible that the child has pyorrhea? Please omit name. M D Nevada

**ANSWER**—In this case, as in almost every case of refractory disease, a personal examination of the patient is important. Without that opportunity the diagnosis is merely speculative. It is assumed that the condition is not due to Vincent's infection or a dietary deficiency since these have apparently been considered. One should make sure that the oral hygiene has been not only stressed but also properly executed. Too often the simplest requirements are overlooked. The mouth should be freely irrigated and kept as clean as conditions will permit.

Next a thorough examination of the blood should be made. Blood diseases are responsible for many baffling oral lesions. The disease known as agranulocytic angina closely resembles Vincent's infection. The blood picture shows a marked reduction in leukocytes and an extremely low percentage of granulo-

cytes. The principal clinical symptoms are ulcerations of the mucous membranes, most frequently in the mouth and pharynx, fever and occasionally jaundice.

If it is certain that the local treatment has been carried out in a satisfactory manner and that there is no blood disease, an allergy expert should be consulted. The interchanging of eating utensils will not transmit pyorrhea, however, the practice is obnoxious for other reasons. It is unlikely that the child has pyorrhea.

#### PERNICIOUS ANEMIA WITH NERVE INVOLVEMENT

*To the Editor*—I am writing to ask whether there is any additional treatment you would suggest for pernicious anemia. The patient is a woman aged 49. She weighs 205 pounds (93 kg) and her height is 5 feet 11 inches (180 cm). The onset of the disease was in December 1931. She received inadequate treatment and several relapses occurred. I first saw the patient in September 1933. The blood count showed red blood cells 3,720,000 hemoglobin 62 per cent (Sahli) white blood cells 7,500 a few poikilocytes and cells of various sizes. At this time she was taking fifteen capsules of Extralin daily. She complained of numbness soreness in the extremities difficulty in walking and various areas of anesthesia in the lower extremities. I began giving injections of 3 cc of Lederle solution liver extract parenteral refined and concentrated into the gluteal muscle every three days. She also took four Lederle iron ammonium citrate capsules daily. The red blood cells rose to 4,340,000 the hemoglobin was 80 per cent in November. November 20 I began giving her 3 cc of Lederle solution liver extract parenteral refined and concentrated intramuscularly daily for five days then every two days for seven injections. The red blood cells rose to 4,920,000 the hemoglobin was 90 per cent. Since then I have been giving her intramuscular injections twice weekly of 3 cc of either Lederle solution liver extract parenteral refined and concentrated or solution liver extract Lilly using a 2 inch needle. The red blood cells have risen to 5,160,000 and the hemoglobin to 90 per cent. There are variations however and at present the red blood cells are 4,710,000 and the hemoglobin is 90 per cent. For three weeks I gave her concentrated liver extract Armour one tablespoonful three times a day with the intramuscular treatment twice weekly but no improvement resulted. The patient feels better and stronger but does not seem to respond to oral or parenteral treatment. Apparently oral administration of liver extract is ineffective for she had taken Extralin for many months along with the parenteral treatment. Dilute hydrochloric acid was given only for symptoms as indicated. Kindly outline additional treatment. Please omit name and address. M D Pennsylvania

**ANSWER**—From the description of the case presented one cannot positively rule out the diagnosis of multiple sclerosis, particularly in view of the loss of sensation in various areas of the lower extremities. Multiple sclerosis is not infrequently accompanied by a moderate degree of anemia, generally of the hypochromic type. In multiple sclerosis the anemia should respond to the treatment outlined, whereas the involvement of the cord would probably be affected very little.

Also in an entirely resistant case one must keep in mind the possibility of the presence of a cord tumor or syringomyelia which may produce changes not unlike those described and may either be a complication of pernicious anemia or be associated with an anemia from loss of blood as an incidental finding.

Assuming that the case is one of pernicious anemia, it is possible that improvement may be hindered by complicating diseases. The common complications are disturbances of the gallbladder, genito-urinary system (such as cystitis generally associated with pyelitis), severe constipation and excessive weight. The latter condition may aggravate disturbances of locomotion. In the presence of complications the intensive treatment outlined might well improve the blood but be insufficient to cause definite improvement in those disturbances associated with spinal cord damage.

Damage to the cord that has persisted for a considerable period of time with inadequate treatment of the anemia is often difficult to control and only a minimal amount of improvement may be expected.

Treatment should consist of sufficient amounts of liver substance to maintain the red blood cell count at a level well above 5,000,000 and this can best be done by means of the intramuscular injections of the concentrated solution of liver extract. It is well to continue the use of the iron unless the hemoglobin level reaches a high point.

In addition, the locomotor disturbances may be improved by exercises, under the direction of a physical therapist trained in this field to retrain the muscle function and to improve the patient's balance.

Complications should be treated and the weight should be reduced.

Under such therapy, improvement may occur only during an interval of several weeks or months and the amount of improvement that may be expected is inversely proportional to the amount and duration of the cord damage as influenced by inadequate treatment.

## BRONCHIECTASIS

To the Editor—Please advise what to do with a patient presenting the following history. A man aged 50 had syphilis for about twenty six years and has taken treatment several times during this period. He uses tobacco but no alcohol. About fifteen years ago he contracted influenza and developed a bronchiectasis that is gradually becoming worse. On account of the constant cough he is compelled most of the time to sleep sitting in a chair. Up to three weeks ago he felt very well but the bronchiectasis commenced to give more trouble and he has developed a headache that is aggravated by coughing. Would you advise treating this man for syphilis? Also outline just what treatment you think necessary. I am able to control the cough with codeine but it causes nausea and makes him feel very uncomfortable. The Wassermann reaction is two plus. He has been this way for years and no amount of treatment has made it change. There are no other symptoms of syphilis except the slight headache and that is not constant. Coughing always produces this headache. Please advise what you think is the best treatment for this man. Please do not mention name.

M D Oklahoma

ANSWER—In the treatment of bronchiectasis, promotion of peroral drainage is of paramount importance and may be obtained either by bronchoscopic aspiration practiced weekly or more often, or by postural drainage carried out two or three times daily, the patient choosing periods when he has the greatest inclination for coughing. The use of opiates is as a rule to be interdicted, because of their inhibitory effect on coughing, the most effective natural means of eliminating retained infected secretions, and because they tend to thicken the bronchial secretions by inhibiting the cellular activity. It has been suggested by the Jacksons that the internal administration of alkalis may relieve coughing more effectively than sedation.

Additional information is essential before determining whether or not this patient should receive antisyphilitic treatment. A two plus Wassermann reaction if repeatedly obtained indicates the presence in the serum of small quantities of reagin and presumably points to the persistence of the syphilitic infection. It has been shown that intermittent treatment, such as this patient apparently received, is more likely to be associated with Wassermann fastness than if the treatment had been continuous, and, if carefully sought for, definite lesions particularly in the cardiovascular or central nervous symptoms, bones or viscera may be revealed. Careful physical, roentgen and fluoroscopic examinations of the heart and aorta, spinal puncture, neurologic and ophthalmoscopic examination, study of the visual fields and close inspection of and if necessary roentgenograms of the bones for periosteal thickening are indicated. Subsequent treatment is dependent on the results of such studies. J Earle Moore's *Modern Treatment of Syphilis*, recently published by Charles C Thomas, Springfield, Ill., presents in an excellent manner methods for treating the various forms of syphilis and may be highly recommended for its practical appeal.

## X-RAYS FOR PRURITUS ANI

To the Editor—In *Queries and Minor Notes* in *THE JOURNAL* February 24 page 638 in reply to M D Ohio suffering from pruritus ani you say that x-rays will stop anal itching in about a month and with absolute safety. Leaving out the safety question which is debatable any proctologist of experience will tell you that when x-rays do help (they are not successful in all cases) they relieve only for a period of several months to return later with a vengeance at which time owing to previous treatment with x-rays it becomes refractive to treatment and well nigh incurable.

MICHAEL CANICK M D Brooklyn

ANSWER—When x-rays are employed with proper judgment for the relief of pruritus of the anal region there should be no danger of untoward effects of any kind. A series of four weekly treatments of 90 roentgens each most certainly will not cause radiodermatitis or lead to sequelae such as atrophy, telangiectasia or keratoses. This amount will produce relief in many instances. If not, the treatment should not be continued because, when four such treatments fail to effect the desired result, additional roentgen treatment is also likely to fail. When relief is obtained, such relief may be permanent or temporary. When the remission lasts many months a recurrence is often relieved by a second series of three or four roentgen exposures of approximately 90 roentgens each. Immediate recurrence or repeated recurrences, or recalcitrant cases are unsuitable for roentgen therapy. In such instances persistent roentgen treatment may lead to injury of the local tissue. There is some clinical evidence to support the belief that injudicious roentgen therapy may cause the disorder to become more refractory, even though the amount administered was too small to injure the tissues detectably. On the other hand there is no definite proof that such cases might not have been equally resistant without roentgen treatment. Irritating topical remedies should be avoided during the administration of even the small doses of x-rays mentioned. The mechanism

by which radiation causes relief in favorable cases of so called essential pruritus ani is not well understood. The action may be physical or psychic or both.

Pruritus ani has, apparently, a variety of possible causes. The itching may be due to a recognizable dermatosis. In the so-called essential cases the pruritus may be evoked possibly by some rectal or intestinal abnormality, diabetes or a psychic disturbance. Certainly one should investigate for the cause and when found an attempt should be made to eradicate it. Roentgen treatment is simply one of a number of therapeutic measures that may be employed in an attempt to obtain relief from itching that at times is distressing and not infrequently for which no definite cause can be discovered.

## CHRONIC CARBUNCLES

To the Editor—A man aged 34 came to me three months ago complaining of several red swollen and painful areas on each thigh. These proved to be carbuncles and were incised and drained. New carbuncles however would appear as the older ones healed. This condition prompted a complete examination. The past history revealed nothing of note the patient having always been healthy. He is a clerk in a haberdashery. The physical examination is entirely negative the tonsils are out and a recent roentgen examination shows that the teeth are in good condition. There is a slight sensitiveness to palpation in the right lower quadrant of the abdomen. Repeated complete urinalyses are negative. Kahn and Wassermann reactions on the blood are negative. February 5 a blood count showed hemoglobin 92 per cent, red blood cells 4,970,000 white blood cells 7,800 polymorphonuclears 75 per cent lymphocytes 24 per cent and mononuclears 1 per cent. A smear from one of the carbuncles showed staphylococci. After several weeks of treatment by incising and draining ultraviolet rays local application of bacteriophage oral administration of tonics a diet rich in vitamins and nourishing foods and plenty of fresh air the patient improved and the carbuncles disappeared. Stannoxyl (a combination of metallic tin and its oxide) was prescribed also but its value is questioned. After a quiescent period of six weeks the carbuncles have reappeared and are now on both the lower and upper extremities. In general I am using the same line of treatment but the condition of the patient does not improve. Your advice and suggestions regarding the treatment of this case would be greatly appreciated. Please omit name.

M D Michigan

ANSWER—Carbuncles are usually large and single. Small ones sometimes occur in series as described in this case, but unless deep infiltration and multiple openings exuding pus develop this classification should not be employed. Syphilis may be suspected, in spite of the negative reactions. Series of gummas are sometimes seen, a number of them developing into large abscesses, but they do not cause much pain. A therapeutic test with mercury and iodides for two weeks should show decided improvement if the condition is of syphilitic origin.

Assuming that the staphylococci found are the guilty factors, the problem of stimulating resistance to them is sometimes a difficult one. Local foci of infection should be eliminated if possible. In the case in question nothing is said of the nose and nasal sinuses. The possibility of a chronic appendicitis is suggested. A careful search should be made for such foci of infection.

In addition to examinations of the urine for sugar, the blood sugar and sugar tolerance should be investigated and appropriate treatment given if they are not normal. Tauber (*Arch Dermat & Syph* 27 198 1933) reported good results from increase of sugar in the diet and intravenous injections of dextrose in a series of cases in which the blood sugar was normal or subnormal.

Autogenous vaccines should be used. There is serious doubt of the specific action of vaccines in these cases. They may act merely as a mild form of foreign protein therapy. The endermic injection of toxins made by the Besredka method may be tried. Other forms of foreign protein therapy, such as sterile milk iodized casein, even intravenous injection of typhoid vaccine sufficient to cause a febrile reaction, may be justified.

An ounce of fresh yeast in a little seltzer water a half hour before each meal is a time-honored remedy.

Finally, a long rest and outdoor life with change of scene are recommended.

## INDUSTRIAL HAZARD FROM ALUMINUM PAINT

To the Editor—May I have any information that is available relative to the danger to health that may result from working with so-called aluminum paint. What are the symptoms and measures for combating it?

M D Nebraska

ANSWER—Metallic aluminum dust is comparatively harmless. Its deposition along the respiratory tract may induce minor irritation, possibly lymphatic blocking within the lungs, and in time an increased amount of noncharacteristic fibrosis. A few instances have arisen in which claims have been made that lead as an impurity in this type of metallic paints has

caused lead poisoning. It is not known that any such cases have been proved decisively. The vehicle in which the metallic aluminum is suspended is likely to be a mixture of various acetates and higher alcohols. Such substances lead to low grade irritation to the eyes, respiratory tract, and the skin. Various painters are known to dilute aluminum paint with such substances as turpentine, leptyne, and various petroleum derivatives. This possibly is technically undesirable in that discoloration of the aluminum may arise. Whenever such dubious and uncontrollable practices are carried out, naturally some additional hazards may arise.

#### BLOOD FLOW THROUGH KIDNEY

*To the Editor*—I would appreciate any information you can give me on the methods for determining the volume of blood flowing through the kidney per minute. I am particularly anxious to know whether there is a method that has as its base the systemic blood pressure. Please omit name.

M D Alabama

*ANSWER*—We presume that the inquirer has in mind the determination of the rate of blood flow through the kidney of man. There is no method that will permit such a study. The study of rate of blood flow passing through the kidneys of experimental animals, while the rate of urine formation is being studied simultaneously, is an old and well established one. It consists in enclosing the kidney in a suitably constructed plethysmograph (called an oncometer), which in turn is connected by rubber tubing to a delicate recording manometer or piston recorder. Even under laboratory conditions in which the oncometer is used a study of the blood pressure gives no idea of the rate of blood flow through the kidney, since changes in the blood flow through the kidney can occur without a change in the general arterial blood pressure; conversely the blood flow through the kidney may vary little, if at all with an increase or decrease in the blood pressure. A schematic account of the use of the oncometer will be given on request.

#### HAZARDS TO HEALTH IN WELDING INDUSTRY

*To the Editor*—A man seen at 4 30 p m complained of coughing, dyspnea and nausea. The temperature was 100 F, the pulse 96 and the respiration rate 26. Moist rales could be heard scattered through both lungs. The patient had a persistent cough and was expectorating a mucopurulent material with a greenish color. He stated that he began welding galvanized iron in an unventilated room at about 12 o'clock. He was using an acetylene torch. About 3 o'clock he was having very marked difficulty in breathing, felt nauseated and was coughing almost constantly. A fellow workman opened a window and fanned him after which he was removed to his home and a physician was called. The following day the patient's temperature was 99.6 F in the morning but dropped to normal and remained so thereafter. The respiration rate and pulse were normal. Examination of the blood showed a total white count of 14,500 with 85 per cent polymorphonuclear leukocytes and 15 per cent lymphocytes. Urinalysis was negative except for plus 1 albumin and the presence of acetone. The patient was still complaining of some dyspnea and an occasional moist rale could be heard through both lungs. On the second day the temperature, pulse and respiration rate were normal and the patient felt well. This case would have been diagnosed influenza without question had the patient not been exposed to the fumes described. Could this condition have resulted from the inhalation of such fumes? Please omit name.

M D Virginia

*ANSWER*—This entire condition might have resulted from the inhalation of welding vapors, but an associated and antecedent infection of the respiratory tract undoubtedly contributed to the condition. The extent to which occupational factors may have influence is now indicated. In burning the galvanized coating off the iron, zinc fumes are produced. Inhaled zinc fumes readily bring about an acute condition representing one form of "metal fume fever." In doing this work with an acetylene torch it is possible that hydrogen arsenide (arsine) may have been present as an impurity in the acetylene. This is not very probable. If present, this toxic agent would have caused general malaise, difficulty in breathing, vertigo, gastrointestinal disturbances and nephritis, among other ailments. Also, the remote possibility exists that hydrogen phosphide (phosphine) might exist in the acetylene as an impurity. This substance in a mild case would occasion about the same manifestations as those attributed to hydrogen arsenide.

Respiratory disorders among welders are quite common. The fumes to which they are exposed, while not invariably leading to characteristic occupational diseases, so irritate the respiratory tract as to promote or accelerate ordinary bacterial invasions. It is quite within reason to attribute the case described in the query chiefly to bacterial action but to recognize that it probably was set in motion and aggravated by the well known injurious fumes arising from welding work and particularly from welding work on galvanized surfaces.

#### CEREBROSPINAL SYPHILIS

*To the Editor*—I have a patient a man aged 45 who shows a four plus Wassermann reaction although treated with full courses of arsenic, mercury and bismuth compounds and the iodides. The lesion was localized as a meningeal syphilis the chief sign being a unilateral ptosis of the eyelid. Under treatment the ptosis disappeared and the patient's general health is much improved. The initial treatment was given four years ago. Would you advise fever therapy, malaria or vaccine? The general constitutional condition is good.

H H Wright M D Keene, Ont

*ANSWER*—It would seem that the major criterion of the patient's condition as regards the nervous system, for which fever treatment has the most favorable results, would be indicated by the condition of the cerebrospinal fluid. It would be wise, therefore, to do a lumbar puncture. If the spinal fluid is normal and the patient is free from symptoms, there would seem to be relatively little reason for fever therapy. If, on the other hand, the cerebrospinal fluid is positive, in spite of the amount of treatment that he has had it would then be wise to give either malaria or some treatment with trypanamide, if malaria is not chosen. In the absence of central nervous system activity, it is questionable how much either trypanamide or fever will do in changing the blood Wassermann reaction.

#### INTERPRETATION OF KAHN TEST

*To the Editor*—A man aged 37 contracted syphilis in 1927. During the next three years he received infrequent treatment. In 1930 his blood Wassermann reaction was 4+ positive. For the next two years he received regular treatment consisting of courses of arsphenamine followed by compounds of bismuth and mercury with rest periods. In February 1933 the blood and spinal fluid Wassermann reactions were negative. He has received no treatment since but blood Wassermann tests have been made every three months. The last report was Wassermann negative, Kahn 3 plus positive. The test was repeated with the same result. Does this indicate a relapse and should the patient receive further treatment? His physical examination is otherwise negative. Please omit name.

M D Ohio

*ANSWER*—The positive Kahn reaction does not necessarily indicate a relapse. It may be that if a Kahn test had been made in February 1933 the result would have been positive also at that time. The Kahn test, being more sensitive than many Wassermann techniques, is often positive in treated cases that give negative Wassermann reactions. But these negative reactions, after months or years, often become positive again. Further treatment appears to be indicated although this step must necessarily be a matter for decision by the physician who knows the physical status of the patient.

#### EFFECT OF CONSTITUTION, DIET AND INTERNAL SECRETIONS ON DEVELOPMENT OF TEETH

*To the Editor*—Can you tell me where I can obtain information about preventive work in tooth development with regard to the position of the teeth? There is a great deal written about tooth straightening in orthodontic literature but little about etiology or correction. I feel that a pediatrician would be able to prevent a great deal of the orthodontic work that is now necessary if he had the knowledge. Dr. Corman O. Edwards of Oakland, Calif., furnishes a device that may be attached to the bottle for treatment of micrognathia and results with this were described in the *American Journal of Diseases of Children*. This seems to me to be a step in the right direction, and I should like more information on the same subject.

G L Johnson M D Englewood N J

*ANSWER*—No doubt ultimately the pediatrician will play a very important part in the prevention of irregularities of the teeth. This, however, will not be possible until the internist establishes quite definitely what part diet, heredity and endocrine secretions play in the general metabolism and particularly in the development of the skeletal system. Dietary deficiency diseases are certainly important factors in the causation of irregularities of the teeth. But even when there is present a well balanced diet as it is understood today, irregularities develop. This suggests the conclusion either that diet does not control everything in the development or that diet is not yet fully understood.

Dr. Hugo R. Rony of the Northwestern University Medical School recently read a paper before the Chicago Dental Society on endocrine disturbances and their effects on the development of the system. This paper which will soon be published in the *American Dental Journal*, is a report of extremely unusual experimental work that is being done now. With reference to nutrition and endocrine secretions, he states: "In the first place the growing organism must be supplied with all the necessary food factors both in amount and quality, enough proteins, fats, carbohydrates and minerals must be available not only for actual consumption but also for deposition into the growing tissues. Furthermore certain vitamins must be taken in sufficient amounts. Also the tissues must be in a healthy condition, congenital or acquired disturbances of the gastro-intestinal tract

of the blood circulation, etc., infectious diseases with toxemia, etc., will injure the growing tissues and inhibit their growth. These conditions being adequate, growth is controlled largely by the endocrine system."

The endocrine glands that exert the greatest influence on growth and development are the pituitary, thyroid, sex and parathyroid glands. In summarizing, Dr Rony states "It appears that the anterior lobe of the hypophysis controls directly by the growth hormone or indirectly by the thyrotropic and sex hormones practically all growth phenomena in the developmental period of life."

Thus, from the information available to date, it appears that hereditary influence and endocrine secretions play by far the more important role in the development of the normal individual. Diet and local disturbances as causes of irregularities have been overestimated in their importance. But until further work is done and the relative importance of each factor is quite well established, it will not be possible basically to change the treatment from the present orthodontic one.

#### CUPS TO REPLACE PADS FOR MENSTRUATION

To the Editor—The enclosed material about the Sanway Cup was turned over to me by one of our nurses for comment and I must say that I am unfavorably impressed by it. I should appreciate your reactions to this sort of thing. It seemed to me extremely undesirable to use such a contraption as well as entirely unnecessary. May I have your opinion relative to the use of Hy Kup described in the enclosed circular?

ELIZABETH C UNDERHILL M D South Hadley, Mass

ANSWER—1 Some patients have said after about six months' use that these cups are less troublesome and more satisfactory than vulvar pads. They cannot be used in virgins because an intact hymen will not permit the admission of such cups. They most likely will not remain in place in women with pronounced cystoceles and rectoceles, and they will not be suitable for women who have a profuse flow of blood with clots unless the cup is emptied frequently. The cup may be used to good advantage by such women as professional dancers or swimmers, provided, of course the hymen has been broken.

2 Instruments that act as a vaginal plug must inevitably retain at least part of the menstrual blood. They are likely to be insanitary and would predispose to infection.

#### POSTOPERATIVE IRRADIATION OF CARCINOMA OF BREAST

To the Editor—Please furnish me with the technic for postoperative irradiation of carcinoma of the breast. In this particular case there are a few nodules in the axilla and several small recurrences in the old scar. Please omit name.

M D South Dakota

ANSWER—The technic for postoperative irradiation of carcinoma of the breast varies markedly in the hands of different radiologists. It also varies depending on whether radiation is administered prophylactically or in the presence of disease. In the particular case mentioned, the technic depends on the extent to which the disease is disseminated. A localized recurrent nodule or group of nodules is treated most effectively by the insertion of removable platinum radium needles. When the recurrences are more extensive and more widespread, external irradiation with x-rays or radium is most efficacious. The external irradiation is frequently combined with interstitial irradiation with considerable advantage. The technic of irradiation is dependent on so many different factors that it is quite impossible to generalize and it is necessary to determine a plan of irradiation for each individual case.

#### CATARACT OPERATION IN EXOPHTHALMIC EYE

To the Editor—Does an exophthalmic eye possess any additional surgical problems when an operation for senile cataract is necessary? Please omit name.

M D Michigan

ANSWER—If a high degree of exophthalmos is present, it is somewhat more difficult than usual to sterilize the conjunctival sac adequately before operation. There is also the added danger of pressure by the lids on the eyeball. This should be combated by an external canthotomy immediately before the Graefe incision. Sutures are used either corneal (Liegard) or conjunctival, in order to prevent subsequent gaping of the corneal wound. Again, owing to the protrusion of the eyeball, there may be a light lagophthalmos. This must be determined before operation and if possible the lids must be closed by sutures which are put into position before the operation on the eyeball is started. It stands to reason that, if the exophthalmos is due to hyperthyroidism the operation should be performed during a remission of the toxic condition. In other respects the lens may be extracted exactly as in a normal eye.

## Council on Medical Education and Hospitals

### COMING EXAMINATIONS

AMERICAN BOARD OF OPHTHALMOLOGY Chicago Sept 8 Application must be filed sixty days prior to date of examination Sec, Dr William H Wilder 122 S Michigan Blvd Chicago

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY Written (Group B candidates) The examination will be held in various cities of the United States and Canada Nov 3 Sec Dr Paul Titus 1015 Highland Bldg Pittsburgh

CALIFORNIA Los Angeles July 23 26 Sec Dr Charles B Pinkham 420 State Office Bldg Sacramento

CONNECTICUT Endorsement Hartford July 24 Sec Dr Thomas P Murdock 147 W Main St Meriden

NATIONAL BOARD OF MEDICAL EXAMINERS The examinations in Parts I and II will be held at centers in the United States where there are five or more candidates Sept 12 14 Ex Sec Mr Everett S Elwood 225 S 15th St Philadelphia

NEVADA Reciprocity Carson City Aug 6 Sec Dr Edward E Hamer Carson City

SOUTH DAKOTA Rapid City July 17 18 Dir Division of Medical Licensure Dr Park B Jenkins Pierre

WASHINGTON Basic Science Seattle July 16 17 Medical Seattle July 19 21 Dir Department of Licenses Mr Harry C Huse Olympia

### Arizona April Examination

Dr J H Patterson, secretary, Arizona State Board of Medical Examiners, reports the written and oral examination held in Phoenix, April 3-4, 1934. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. One candidate was examined and passed. Three physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad (1933)
Rush Medical College		
School	LICENSED BY RECIPROCITY	Year Grad with Reciprocity (1917) California (1929) * California (1903) N Carolina
Chicago College of Medicine and Surgery		(1917) California
University of Illinois College of Medicine		(1929) * California
University of North Carolina School of Medicine		(1903) N Carolina
School	LICENSED BY ENDORSEMENT	Year Grad of (1928) N B M Ex
Harvard University Medical School		(1928) N B M Ex
* Granted temporary permit. License will be issued when basic science examination is completed.		

### Wisconsin Reciprocity Report

Dr Robert E Flynn, secretary, Wisconsin State Board of Medical Examiners, reports 5 physicians licensed by reciprocity at the meeting held in Milwaukee, April 5, 1934. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad with Reciprocity (1923) Illinois (1931) Mississippi (1900) Illinois (1931) Penna (1899) Penna
General Medical College Chicago		(1923) Illinois
University of Illinois College of Medicine		(1931) Mississippi
Hahnemann Med Coll and Hospital of Philadelphia		(1900) Illinois
University of Pennsylvania School of Medicine		(1931) Penna
Woman's Medical College of Pennsylvania		(1899) Penna

### California February-March Examination

Dr Charles B Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held in Los Angeles, Feb 27-March 1, 1934. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. Sixty-four candidates were examined. 56 of whom passed and 8 failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent (1933)
University of Arkansas School of Medicine		(1933)	84.1

## Book Notices

**Rose and Carless' Manual of Surgery.** Fourteenth edition revised by Cecil P. G. Wakeley D.Sc. FRCS. FRS. Surgeon Kings College Hospital and John B. Hunter M.C. M. Chir. FRCS. Surgeon Kings College Hospital. American (fourteenth) edition edited by W. T. Coughlin B.S. M.D. F.A.C.S. Professor of Surgery and Director of the Department of Surgery St. Louis University School of Medicine. Cloth. Price \$9. Pp. 1468 with 676 illustrations. Baltimore: William Wood & Company 1933.

Beginning with its first edition, which appeared in 1898 the Rose and Carless manual has justly been considered as a standard textbook on surgery. Its popularity with teachers and students is attested by the fact that it has passed through thirteen editions. Because of certain differences in the curriculums here and in England the present edition has been especially revised and rearranged. The general aim has been to present to the student the principles and science of surgery rather than its practice and art. Because of recent advances, some of the chapters had to be entirely rewritten and much new material had to be added. The chapter on thoracic surgery is entirely new, the subject of fractures is enlarged by the inclusion of Böhler's method of treatment, the newer methods of roentgenologic study of the urinary tract were added. The curtailment of chapters on bacteriology, immunity and inflammation is an advantage, as these subjects are more properly treated elsewhere in the curriculum. The publishers are to be congratulated on the appearance of the new volume, which is a great advance on the preceding edition. This was accomplished by printing it on a highly surfaced paper with a resulting clearer print and illustrations. From a pedagogic point of view the volume is abreast of the times and the subject matter is logically arranged and ably presented. It will undoubtedly continue to be one of the standard textbooks on surgery.

**Zur Kenntnis der Hirnveränderungen bei der normalen Altersinvoluktion.** Von Nils Gellerstedt. Med. Lic. Inaugural Dissertation zur Erlangung der medizinischen Doktorwürde. Uppsala: Aus Uppsala Lakareförenings Förlag. N. F. Band XXXVIII. Haft 56. Paper. Pp. 408 with 74 illustrations. Uppsala: Almqvist & Wiksells Boktryckeri A. B. 1933.

Neurofibrillary cell changes with formation of so called senile plaques ("drusen"), accumulation of catabolic products in the ganglion cells changes in the myelin nerve fibers and other less striking phenomena are considered typical of involutional insanities (senile and presenile). The specificity of such changes may be questioned, since Gellerstedt was able to demonstrate similar changes in what may be called normal senility. He came to such a conclusion after a careful microscopic study of the brains of fifty persons of the average age of 65 and

contrasted the resulting observations with those from similar studies in "pathologic" senility and young individuals who had died from somatic disorders, accidents or some psychic disorders. The facts obtained were carefully tabulated, subjected to a critical study and richly illustrated by photomicrographs and colored drawings. The book gives an excellent review of the condition of the central nervous system in old age, but in some of his views the author was evidently too greatly influenced by German neuropathologists. For instance, the author is of the opinion that the brain changes in senile states are for the most part of vascular origin, the result of arteriocapillary fibrosis, which secondarily causes parenchymatous and other types of lesions—a view that is hardly acceptable.

**Our Mysterious Life Glands and How They Affect Us. A Popular Treatise on Our Glands and Their Secretions—What They Do to Us How They Affect Our Health Growth Appearance Temper. Mentality and Character Including the Vitamins.** By William J. Robinson Ph.D. M.D. Consultant to the Department of Genito Urinary Diseases and Dermatology, Bronx Hospital. Cloth. Price \$2.50. Pp. 291 with illustrations. New York: Eugenes Publishing Company Inc. 1934.

The physician who undertakes to reduce a scientific subject to a form for popular consumption by lay readers encounters a great deal of difficulty. By adhering strictly to his science he risks the loss of popularity, and if he strives for the popularity his science suffers. In his new book, Robinson turns a versatile pen to a profound subject with the purpose of bringing lay readers down to the present. "Our Mysterious Life Glands" is not so mysterious in the relating as in the announcing. The physiology of these organs is told in a stereotyped way and their dysfunctions are sketchily related. The sex glands naturally come in for more detailed exposition and there is a wealth of descriptive matter draped around the gonads, for instance, homosexuality, sterility, impotence and the present status of rejuvenation. The author is severely critical of those who have ventured into the speculative field of the relation of the glands to personality. Plainly he does not believe in such adventuring. He thinks it is not scientific, and this may be true. It diverts the mind of the lay readers from the parts in which they are naturally interested and causes more or less mental confusion. The dangers are recited with much display of the first person singular. The author does not believe, for instance, that the endocrine glands, although their potency is admitted, can ever make a wise man out of a fool, but he ignores the reciprocal that the glands have not infrequently made fools out of wise men.

**Lehrbuch der operativen Geburtshilfe für Ärzte und Studierende.** Von Prof. Dr. Georg Winter und Prof. Dr. Josef Halban. Vorstand der Gyn. Abt. des Krankenhauses Wieden in Wien. Unter Mitwirkung von Prof. Dr. W. Benthlin und Prof. Dr. H. Naujoks. Second edition. Paper. Price 40 marks. Pp. 556 with 294 illustrations. Berlin & Vienna: Urban & Schwarzenberg 1934.

In the preparation of the present edition the services of Halban were enlisted, and this able obstetrician and gynecologist has made many valuable contributions to the book. The number of pages has been increased and fifty-four illustrations have been added. As was mentioned in the review of the first edition (THE JOURNAL, Jan. 28, 1928, p. 316), the book is an enlargement of the chapter on the same subject written by Winter for Halban and Seitz's monumental *Biologie und Pathologie des Weibes*. In the first part of the book there is a discussion on general technic, including asepsis and antisepsis, the preparation of the patient and physician, anesthesia and instruments. Operations are divided into those performed during pregnancy, during labor and during the puerperium. There is also a chapter on the management of injuries fetal as well as maternal. The names of the authors are a sufficient guaranty that the contents are readable and instructive, because both men have had as extensive an experience in obstetrics as any authorities in the world. The illustrations are abundant and instructive but in a large number operations are pictured performed with ungloved hands. A disproportionately large number of illustrations (32 out of a total of 282) are devoted to destructive operations on the child. All forms of cesarean section are described, but the transperitoneal operation is the one of choice. The use of the Kielland forceps is described and illustrated in detail. Unlike American publishers, the German and Austrian publishers issue books both bound and

unbound. The latter are usually held together by a paper cover. The copy reviewed was so poorly glued that it fell apart during the first few minutes the book was being read. The difference in cost between the bound and the unbound book is 3 marks and, based on the total cost, 43 marks, is small compared to the discomfort of trying to read and keep permanently a mass of loose pages. Furthermore, the price of the book is too high. However, for those willing to be extravagant the book is decidedly worth while owning.

**Your Germs and Mine. The Story of Good and Bad Microbes.** By Berl ben Meyr. Cloth. Price \$2.75. Pp. 389 with 34 illustrations. Garden City: Doubleday, Doran & Company, Inc. 1934.

The book is broader in scope than its title promises. It deals primarily with germs, but only as a starting point for an excellent discussion of personal and community hygiene as these concern themselves with communicable diseases. A good discussion of useful germs is the principal feature of the book. The chapters on milk and water are exceptionally clear and comprehensive. The discussion of immunology is refreshingly conservative as regards some of the immunizing procedures that are of more or less doubtful value. The author has been able to infuse human interest into his style without sacrificing accuracy and to speak his mind plainly about some of the modern shortcomings of individuals and communities with respect to health without at the same time becoming sensational. He might profitably have enlarged on the subject of ringworm, instead of hooking a sentence or two about it on a chapter where it does not logically belong and then leaving the reader up in the air as he turns the page to find a new chapter heading and nothing much about ringworm except that it is sometimes confused with the ground itch of hookworm infestation. This book should make excellent supplementary reading for high school or college students for whom a general knowledge of bacteriology is desired but for whom no great amount of technical detail is necessary. It would also give any citizen an excellent idea of the reason for having a health department in a city and also why it is important to have, not a health department in name only, but one in fact. Other authors might have chosen somewhat differently in deciding on what diseases to treat at length and what to touch on briefly in the "omnibus chapter," but that is and must remain a matter of opinion. The book is well made, adequately illustrated and well indexed.

**Schlafmittelmissbrauch.** Von Dr. Kurt Pöhlisch, Privatdozent an der Universität Berlin und Dr. Friedrich Panse, Oberarzt an den Wittenauer Heilstätten. Boards. Price 9.60 marks. Pp. 170 with 2 illustrations. Leipzig: Georg Thieme, 1934.

The abuse of hypnotics in Germany has grown tremendously in recent years and is increasing. Among hospital patients in Berlin, chronic intoxication from hypnotics almost equals that from chronic alcoholism. The authors speak mainly of their own cases and of cases from the German literature. Relatively few cases from foreign literature have been included. Their study is important, because the drugs studied have a wide use also in America. They divide their investigation into a study of single excessive dosage from 1925 to 1932, and chronic intoxication or habituation mainly from 1903 to 1932. The first group almost exclusively comprises cases of attempted suicide. In the second group the abuse of the drugs had lasted one or more years, usually with marked psychic effects. In both groups the results of the hypnotic studied are given in statistical form for each year and summarized for the total period. The age of habitues varied from 15 to 75, but by far the greater number were between the ages of 20 and 50 years and about 70 per cent of these were psychopathic cases. A study of the symptom complex of single dose abuse of the various hypnotics in relation to their chemical constitution is based on 707 cases of intoxication. The authors discuss all the well known and a number of relatively new preparations such as evipan. Under the habitual use of large doses they omit chloral hydrate, paraldehyde, amylene hydrate and the sulphur-containing hypnotics, because they discussed these in 1928. They discuss the use of veronal, luminal, phanodorm, somnifen, dial, allonal, veramon, the adalin group, bromural and combinations of two or more of these with other preparations. Many clinical cases with histories and symptoms are cited.

The authors discuss the genesis and development of the chronic abuse of hypnotics, using statistical, psychologic and clinical-pathologic methods. Their main conclusions are that 1. Neurosis is an important genetic factor, as is also alcoholism and morphinism. However, the psychically robust may also be victims. 2. All hypnotics are habit forming, and their habitual use demands an increasing dosage. 3. Habitues may take hypnotics day after day without sleep development. 4. Instead of sleep, symptoms may develop which vary in different persons, also with different preparations somewhat as follows—agreeable fatigue, lazy euphoria, sleepy indifference, pleasant sleepy stupor, and occasionally, especially with phanodorm, drunken-like cheerfulness. 5. From continued use there gradually develops a clinical picture that resembles the psychic condition of chronic alcoholism.

The authors finish with advice on the prevention of the abuse of hypnotics which is universally applicable. Patients that most need these drugs are the type most likely to misuse them. Consequently physicians should bear this in mind when they prescribe hypnotics. Again, the prescription should be limited to about five doses. Original packages and prescriptions that contain more than this number may lead to habit formation. They point out that with the increase in the number of hypnotics on the market there is a corresponding increase in habitues. There are too many hypnotics available. The book presents a strong argument against self medication and against the promiscuous advertising of a valuable but dangerous group of drugs. The results of this important study should be available to the public as well as to the physician.

**Handbuch der experimentellen Pharmakologie.** Herausgegeben von A. Heffter. Fortgeführt von W. Heubner, Professor der Pharmakologie an der Universität Berlin. Band III, Teil 2. Allgemeines zur Pharmakologie der Metalle Eisen, Mangan, Kobalt, Nickel. Paper. Price 96 marks. Pp. 621, 1562 with 66 illustrations. Berlin: Julius Springer, 1934.

The completion of another section of this monumental work on experimental pharmacology is a notable event of world wide significance and it will be particularly welcomed by those to whom the *Handbuch* has become an indispensable basis and guide in their work. It may seem still more notable to the uninitiated that it requires almost 900 closely printed pages to do justice to the pharmacology of the "iron group," which includes merely the four metals iron, manganese, cobalt and nickel, and, of course, the discussion of iron occupies over two thirds of the book, or 600 pages. Likewise welcome is the announcement that the other two sections of the third volume will soon be ready for publication, and, last but not least, that the index, the lack of which greatly lessened their value to the possessors of the previous volumes of the series, is in active preparation. To cull from the mass of facts presented by the book only a few of general interest, it may be noted that iron plays the important part in life processes that it does not because it is abundant in the earth's crust—silicon and aluminum are much more important quantitatively—but because of the following combination of properties, which no other metal displays: (1) water solubility, (2) possibility of formation of colloidal protein compounds without denaturing of either the protein or the iron, (3) ease of oxidation from bivalent to trivalent iron, (4) ease of reduction from trivalent to bivalent iron, and (5) the difference in the pharmacologic action of these two oxidation stages, of which the one is the inactive passage form while the other makes the life processes of the cells possible. The ferrous salts, like all bivalent metals, have little affinity for anions, they are rather poorly hydrolyzed and they have but little tendency to the formation of complexes. The ferric salts are strongly hydrolyzed, are always acid because they unite with the hydroxyl ions of water, and have a tendency to the formation of complex compounds, many of which are colloidal. Ferric salts are protein precipitants, while ferrous salts are not or when they do precipitate the combination is reversible, the protein not being denatured. It is only in its ferrous form, therefore that iron is absorbable. Ferric salts must be reduced in the stomach to ferrous salts before they can be absorbed and, because of limited stay in the stomach only a small portion of the ferric salt is thus converted. Hence ferrous salts are absorbed to a much greater extent and are much more valuable as hematinics than the ferric salts.

**The Road to Adolescence** By Joseph Garland M.D. Physician to Children, a Medical Department Massachusetts General Hospital. Cloth Price \$2.50 1 p. 298 with 11 illustrations. Cambridge: Harvard University Press 1934

This is a logical, sensible and sympathetic discussion of adolescence. The book contains a simple discussion of heredity, environment, growth and development, anatomy, care of the body, nutrition and diet, recognition and care of sickness, vaccines and serums, first aid, relationship of home, school and camp special problems in education and, under the title "As the Twig is Bent," a philosophy of home life which every parent ought to read. The author emphasizes that the plasticity of children's minds is not the plasticity of inanimate material but of living tissue. Good reading is suggested, play and discipline are helpfully discussed, and so is sex instruction.

The book is exceptionally well written, as would be expected by any reader familiar with the author's previous work *The Youngest of the Family*. Among numerous books on health which pour from the presses of the publishers, this one stands out as a work of exceptional merit. Though it is written for parents, no mistake would be made by physicians, teachers, social workers and juvenile court officers in reading and digesting it.

**Lehrbuch der Inneren Medizin** Von G. v. Bergmann (mit F. Stroebe) R. Doerr H. Eppinger und anderen. Band I und Band II. Second edition. Paper. Price 45 marks. Pp. 914 with 144 illustrations. Pp. 794 with 136 illustrations. Berlin: Julius Springer 1934

That within the space of only three years a new edition of this two volume practice of medicine totaling about 1700 pages should be required speaks for its well deserved popularity. This is not merely a reprint but is enlarged and has been partly rewritten. Thus, a chapter on the general and special pathology of the diaphragm by Hans Eppinger has been added, which even though short brings into clear view existing knowledge of diaphragmatic disease, mostly of recent origin and largely the result of roentgen investigation. While one cannot help feeling almost sorry for the medical student who must find his weary way through the intricate patterns laid down in this book—many of them in fine print—one also feels that when he has done so and has mastered its contents with German thoroughness he has achieved a complete and scientific understanding of the medicine of today.

**The Professional Training of the Hospital Dietitian** By Helen Clarke Ph.D. Teachers College Columbia University. Contributions to Education No. 602. Cloth. Price \$1.50 1 p. 96. New York: Bureau of Publications Teachers College Columbia University 1934

This is the report of a survey and study of training for hospital dietitians as offered by schools of collegiate rank in 1931-1932. The survey included visits to twenty-five hospitals, and the report contains well compiled summaries of all types of instruction for dietitians in the United States. It also includes chapters on the hospital dietitian, the dietitian intern, college curriculum for hospital dietitians and college subjects and trends in academic training. Appended is a well prepared list of colleges, universities and technical schools that give work for prospective dietitians, with information concerning each school. There is also an outline of courses approved by the American Dietetic Association and a list of courses approved for dietitian interns. The work of institutions was judged by curriculums suggested by the American Dietetic Association.

**Mat i Ditya** Mother and Child. Paper. Price 5 rubles. Pp. 30 with illustrations. Leningrad: All Union Society for Cultural Relations with Foreign Countries jointly with the Crèches Board of the Leningrad Public Health Department 1933

As an instrument of propaganda, this production is interesting. The large size of the pages 12 by 17 inches the profusion of photographs, which constitute, with their brief legends, the entire pamphlet, and the good quality of the photography indicate the practiced propagandist. It is hard to appreciate how any thinking person could be caught by such palpable bait. The elaborate preparations for the care of the expectant mother for the parturient woman and for the puerperium, plus the mass production methods for the care of the infants, are stressed. Legalized abortion is portrayed. Nothing is said

about the equivocal position of women in a society where divorce is as easy as saying good morning, or about the crowded living quarters, inadequate food and forced labor, for which the elaborate vacation homes would seem but sorry recompense. To the socialistically minded traveler in Russia, who gets his impressions from what officials say, in towns where he does not stay long enough to investigate conditions for himself, this pamphlet might be convincing. It is claimed on the closing page that "the position of women in Soviet Russia is at the present time such that it can be considered ideal (perfect) from the point of view of the most advanced countries."

**Recent Advances in Vaccine and Serum Therapy** By Alexander Fleming F.R.C.S. Professor of Bacteriology in the University of London and G. F. Petrie M.D. Bacteriologist in charge Serum Department Lister Institute Elstree. Cloth. Price \$4. Pp. 463 with 5 illustrations. Philadelphia: P. Blakiston's Son & Company Inc. 1934

There has been a growing demand for an authoritative and concise treatise on the subject of vaccine and serum therapy, and this volume is a timely addition to the recent advances series. The book covers the general considerations on the production and use of serotherapy, the specific use in various diseases, including those due to filter-passing viruses, specific and nonspecific vaccine therapy and active immunization. While many critical readers will not be prepared to accept some of the statements in regard to the success of vaccine therapy in some diseases, the author of this section carefully distinguishes between clinical and experimental evidence. The book is well balanced in fundamental information and clinical application, and the reader will find it authoritative and clearly presented. It is recommended for both the student and the practitioner of medicine.

**The Mammalian Red Cell and the Properties of Haemolytic Systems** By Eric Ponder. Volume VI. Protoplasma Monographien. Herausgegeben von R. Chambers usw. Cloth. Price 22.50 marks. Pp. 311 with 52 illustrations. Berlin: Gebrüder Borntraeger 1934

The author is well prepared to present this subject by virtue of his extensive researches. It is not a book of applied data and such subjects as the chemistry of hemoglobin and its role in respiration, the clinical significance of changed permeability of the red cell, and other subjects have been purposely omitted. The treatment is entirely in an academic manner, and while this textbook contains valuable data its use will be almost confined to reference purposes. The book covers the number, dimensions, shape, structure, chemical composition and metabolism of the mammalian red cells. Permeability and the phenomenon of osmotic hemolysis and the properties of simple hemolytic systems are next discussed. Various forms of hemolysis are considered as well as the fundamental factors governing their behavior. There is an extensive and well selected bibliography for the reader who wishes to go beyond the confines of the book. The facts presented are critically assessed and clearly presented. A vast amount of material is excellently correlated and summarized. The chief value of the monograph will be as a work of reference, for which it should serve a valuable purpose.

**Constructive Eugenics and Rational Marriage** By Morris Siegel M.D. Cloth. Price \$2.50. Pp. 196 with 12 illustrations. Toronto: McClelland & Stewart Ltd. 1934

While one may sympathize with the earnest purpose of the author to improve the quality of the race and may agree with him in his basic hypothesis that a constructive program of eugenics is needed and that rational marriage is earnestly desired, one cannot share all his opinions. There is nothing essentially new in his proposal that there shall be more extensive study of family pedigrees. One may perhaps be pardoned for entertaining doubts as to the practical nature of his suggestions for constructive eugenics. He seems to desire a return to the nineteenth century method of having prospective mates chosen by the parents of the young couple and believes that such arranged marriages are more selective and rational than those which are entrusted to the young people themselves. The value of a federal or, in Canada, a dominion, eugenic bureau may well be doubted, though in theory it looks like a means of getting a start on a universal study of family

pedigrees The book offers little or nothing that is new, and the subject has been covered so much better in other works that the addition of this book to a health library would not seem to be a necessity

Contribución al estudio anatómico clínico del cáncer del pulmón comenzo clínico por una óstoa artropatía hipertrofiante pneumica Por el Dr Pedro A Castillo profesor de clinica medica Trabajo de la Catedra de Clinica Medica Publicado en la revista Vida nueva en los numeros de abril y mayo de 1933 Paper Pp 247 with 89 illustrations Havana [n d]

This monograph, based on seven personal cases, is a study of the clinical manifestations and pathologic observations The author emphasizes the fact that symptoms are often late, are varied, and include those of toxic absorption His careful study of his own material makes this a worthy contribution to the subject of carcinoma of the lung, which is attracting increasing attention by its apparent marked increase in incidence

## Medicolegal

**Malpractice Sloughing of Tissue Following Subcutaneous Injection of Dextrose Solution**—The plaintiff, a woman approximately 65 years of age, was operated on by Dr Ward, July 27, 1928, for appendicitis The operation revealed that the appendix had ruptured and that the plaintiff was "in the last throes of peritonitis" Following the operation, in order to save the life of the patient, a saline solution containing 10 per cent dextrose was injected into the patient's thighs Owing to the toxic condition of the plaintiff, the intravenous method of injection could not be used, it was concluded, since her circulation was failing and since such injections would overload "the already poisoned heart" Following the injections, there was a sloughing of the tissues at the places where the injections were made Thereupon the plaintiff sued the Hahnemann Hospital, the extern at the hospital who administered the injections, a nurse who assisted him with the injections, Dr Ward, and Dr McGavack, the attending physician who administered the anesthetic A non-suit was granted as to the nurse The jury rendered a verdict for the hospital and the extern but gave judgment against Drs McGavack and Ward, who thereupon appealed to the district court of appeals, first district, division 2, California

The main question before the court was whether the evidence was sufficient to sustain the verdict against the physicians There was no evidence, said the court, that the diagnosis made by the physicians was not entirely correct The paramount duty of the physicians under the circumstances was to endeavor to save the life of the patient There was no evidence to challenge the judgment of the physicians in determining that an injection of a solution containing 10 per cent dextrose was essential to accomplish that purpose There was no evidence to show that in the condition in which they found the plaintiff a 10 per cent solution could have been injected in the veins without defeating that purpose Under these circumstances, said the court it certainly was not malpractice to save the patient's life, even though this was accomplished by the subcutaneous injection of a solution containing a higher percentage of dextrose than is ordinarily so injected, and even though sloughing resulted at the point of injection It is a matter of common knowledge, said the court, that the selection of a method of treatment is a matter of judgment and opinion on which members of the medical profession will often honestly differ There was no suggestion that the defendant physicians did not possess the requisite skill nor that they did not exercise their best judgment It was contended, however, that in the selection of the method of treatment the physicians were required to keep within recognized and approved methods No witness for the plaintiff, said the court stated what were the recognized or approved methods for the treatment of the plaintiff's condition following the operation On the other hand, several medical experts testified for the physicians that the method of treatment selected was the recognized and approved method of treatment for the condition existing Even assuming

said the court, that the medical testimony offered by the plaintiff was in conflict with the opinions of the several medical experts called by the defendant-physicians, the case presented was one showing that the medical experts were at variance in their opinions Under such circumstances, the court continued, the defendant-physicians could not be held liable if they acted within the reasonable limit of either opinion In *Dahl v Wagner*, 87 Wash 492, 151 P 1079, the court said

It has been the uniform holding of this court that where doctors of equal skill and learning being in no way impeached or discredited disagree in opinion upon a given state of facts the courts cannot hold a defendant in a malpractice suit to the theory of the one to the exclusion of the other It is enough if the treatment employed have the approval of at least a respectable minority of the medical profession who recognized it as a proper method of treatment

To hold otherwise, said the California court, would confine physicians in their selection of methods to the use of those methods if any, which have the universal approval of all the members of the profession New or different methods, having the recognition and approval of a minority, including many of the most able practitioners, could never be employed without the risk of a charge of malpractice resulting therefrom The progress of the medical profession should not be obstructed by placing such an unreasonable limitation on the selection of methods of treatment

The judgment of the trial court was therefore reversed, with directions to enter judgment in favor of the physicians—*Callahan v Hahnemann Hospital et al (Calif)*, 26 P (2d) 506

**Insanity Criteria of Criminal Responsibility**—The appellant, Cole, was convicted of murder and appealed to the Supreme Court of Mississippi He contended, among other things, that the trial court committed error in stating in the presence of the jury that

I hold as a matter of law that the only absolute defence of insanity known in the State of Mississippi is paranoia That is just real flat insanity not temporary so if you are pleading insanity the only insanity I recognize is paranoia That is real insanity not just a lapse of memory or just a sudden forgetting of anything just real insanity, known as paranoia in the medical profession

This statement of the trial court was erroneous, said the Supreme Court The true test of a defendant's criminal responsibility is stated in *Grisson v State*, 62 Miss 167, as follows

The test with us in this class of cases is the capacity to distinguish between right and wrong and we know no difference in this regard between total and partial insanity If the disease goes to the extent of breaking down the distinction between a knowledge of right and wrong it is immaterial whether the sufferer be totally or only partially insane on other subjects Irreconcilable conflict in the language of the instruction is created by the insertion of the words if the accused killed the deceased with malice There can be no such thing as malice without mental accountability and this cannot coexist with an incapacity from mental disease to distinguish between right and wrong

The judgment of the trial court was reversed and the case remanded—*Cole v State (Miss)*, 150 So 757

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

#### American Journal of Cancer, New York

21 1252 (May) 1934

\*Cyclomastopathy. Physiopathologic Conception of Some Benign Breast Tumors with an Analysis of Four Hundred Cases. R. L. Oliver and R. C. Major. Baltimore—p. 1.

Further Evidence in Support of the Somatic Mutation Hypothesis of the Origin of Malignancy. M. R. Curtis, W. F. Dunning and F. D. Bullock. New York—p. 86.

Cancer Cells in the Blood Stream. E. H. Pool and G. R. Dunlop. New York—p. 99.

Three Tumors of the Thyroid. C. W. Lester. New York—p. 103.

**Cyclomastopathy**—Oliver and Major present a study of the case histories and pathologic material of 400 cases of clearly benign tumors of the breast, previously classified in their laboratory under fibro adenoma, intracanalicular myxoma and cystic adenoma. The authors believe that the tumors mentioned are not true neoplasms but are localized masses of hypertrophied and hyperplastic breast tissue, with or without involution. The term cyclomastopathy is offered as a designation for the entire group of breast lesions which present excessive connective tissue or epithelial proliferation, or both, in response to growth stimuli or as a manifestation of abnormal involution following normal response. The term eccyclomastoma is offered as a designation for localized areas of cyclomastopathy which give rise to palpable masses or to symptoms. The peak of age incidence for all cases is reached between the age of 20 and 25 years. Women who have borne children outnumber those without children, two to one. Eccyclomastoma has a predilection for the upper, outer quadrant of the breast. A lump in the breast is the predominating symptom, occurring in 83 per cent of cases. Pain occurred in 35 per cent and pain appearing or becoming intensified at the time of the menstrual period occurred in 15 per cent. The average duration for all cases was thirty-six months, for the fibro-adenoma group, forty-four months, and for the intracanalicular myxoma group, thirty-one months. There was no significant racial difference. Movability of the mass was described in 56 per cent. In 15.75 per cent of the total number of cases the masses were multiple, involving one or both breasts. In 5.7 per cent the mass occurred in a generally lumpy breast. Dimpling of the skin was observed in eleven cases and retraction of the nipple in nine cases. In cases in which a preoperative diagnosis was made the lesion was considered benign in 94 per cent. The operation of choice was simple excision with a zone of surrounding breast. When the size of the mass demanded it or when the diagnosis of malignant growth or of possible malignant process was made, amputation or the complete operation was done (12 per cent). The results of 188 followed for more than one year after operation are tabulated.

Carcinoids of the Appendix. A. V. St. George. New York—p. 297.

\*Method of Diluting Antigen in Relation to the Wassermann Reaction. J. A. Kolmer and Carola E. Richter. Philadelphia—p. 301.

Clinical and Pathologic Findings Following Warfare Gassing. P. B. Matz. Washington, D. C.—p. 309.

**Hyperpyrexia Following Intravenous Therapy**—Banks points out that the reaction that follows the intravenous administration of solutions is an entity characterized by a prompt

rise of temperature in extremely high degree and usually associated with a severe rigor lasting from twenty to thirty minutes. This clinical picture is not to be associated with shock and is entirely distinct from it. Intravenous reaction has a definite, specific, etiologic factor. This factor is the introduction of dead or living products of bacterial growth or cultures of *Pseudomonas scissa* or *ureae* into the blood stream of the patient. These organisms were isolated in pure culture from the offending solution, reinjected into the same person and produced the same clinical picture. It was not possible to recover the organism from the blood stream of the individual suffering from a reaction, even though cultures were made at various times during the rigor. The pyrogenic substance may be used as a therapeutic agent to produce hyperpyrexia.

**Diluting Antigen for the Wassermann Reaction**—Kolmer and Richter believe that the manner or method of diluting extract for the Wassermann test has a slight but definite influence on antigenic sensitiveness. Turbid emulsions of antigens secured by slow or gradual dilution with sodium chloride solution are more antigenic than opalescent emulsions prepared by rapid dilution. Turbid emulsions of antigens prepared by adding extract drop by drop to the sodium chloride solution, with constant shaking, are more antigenic than turbid emulsions prepared by adding small amounts of the solution to the antigen with constant shaking. There is no detectable influence in the manner of diluting the Kolmer antigen on the hemolytic properties of this extract. Turbid emulsions of antigens prepared by slow dilution are sometimes slightly more anticomplementary than opalescent emulsions prepared by rapid dilution. In the Kolmer modification of the Wassermann test it is recommended that the antigen be diluted by adding it drop by drop to the required amount of sodium chloride solution with constant shaking to secure the maximum of turbidity as originally described in this method.

Historical and Biologic Evolution of Human Diet. S. S. Altshuler. Detroit—p. 215.

**Congenital Pericolic Membrane Syndrome**—Bueermann discusses a symptom complex simulating chronic appendicitis, for which appendectomy has often been performed with a persistence of pain referable to the right side. The author has five axioms to be substantiated before one may assume that a clinical entity due to the presence of harm producing pericolic membranes and bands exists. Assuming that the usual differential diagnostic factors have been ruled out: 1. There must be a definite anatomic basis in or about the right half of the colon to produce the symptoms that persist after appendectomy for chronic appendicitis. If anatomic in nature, there must be an abnormal situation present such as constriction or rotation, in order to produce an altered physiology of the functions of

the colon 2 If the syndromes of "chronic appendicitis" and congenital pericolic membranes and bands overlap, the syndrome arising from the presence of constricting, congenital pericolic membranes remains as a relatively pure clinical syndrome when only the appendix has been removed 3 If the syndrome arising from the presence of constricting pericolic membranes still is present after appendectomy, correction of the causative factor by sectioning the constricting membranes and bands should relieve the patient 4 If the symptoms considered indicative of congenital pericolic membranes can be classed as a "syndrome," it should be recognizable as such in all age groups 5 If abnormal attachments of pericolic membranes are congenital in nature, familial or hereditary tendencies can be demonstrated in a reasonable number of patients, i. e., the same syndrome should occur in the parent and the child in a certain proportion of subjects A number of instances of father-and-son, and mother-and-daughter similarities have been analyzed In none of these instances had the similarity been recognized until the symptom complex had been outlined The "exercise symptom" relationship then became apparent only in those definitely affected, even to nonrelief by appendectomy The author terms this symptom complex the "pericolic membrane symptom"

The Influence of the Thyroid on the Action of Gonad Stimulating Hormones C F Fluhmann San Francisco —p 498

Observations of Intestinal Movements—White and his associates observed the proximal colon, ileocecal sphincter and terminal ileum in an unanesthetized human subject No definite antiperistalsis was seen in the proximal colon The ileocecal sphincter was relaxed much of the time The relaxed sphincter may respond to a peristaltic wave in the distal ileum with an

immediate or with a delayed contraction or series of contractions, or it may show no response The sphincter may show rhythmic activity in the absence of ileac peristalsis Rhythmic segmentations of the ileum persist during the passage of a peristaltic wave The wave of peristaltic contraction is not preceded by a wave of inhibition Many of the peristaltic waves of the terminal ileum die out shortly before reaching the sphincter The sphincter is consistently relaxed by epinephrine, its activity may be somewhat increased by pilocarpine Solution of pituitary produces some increase in activity of the colon and a diminution in the tone and rhythmic activity of the ileum, peristalsis of the ileum may be either increased or decreased

Stimulation of Mammary Gland Development—Weichert and Boyd compared the mammary glands of pregnant rats fed 0.5 Gm of desiccated thyroid daily, beginning with the first day of pregnancy with normal controls Although some stimulation of the mammary gland is recognized in the animals fed thyroid even on the fifth day of pregnancy, an extraordinary increase of mammary tissue occurs between the seventh and ninth days From the ninth day until the end of pregnancy the series of animals fed thyroid showed a marked difference not only in the amount of mammary tissue but in the earlier appearance of secretion in the alveoli The authors suggest that under conditions of heightened metabolism resulting from thyroid feeding the normal estrin level may be lowered, thus removing the inhibitory effect of the estrin on the hypophysis, at least to a degree That organ may thus elaborate its hormones to a greater extent than normal The corpus luteum and hypophyseal hormones are therefore in all probability present in relatively greater concentrations than in the normal animal, the mammary glands responding to the altered conditions by exceptionally rapid development

**Cytology of Secretions in Allergy**—It has been the experience of Hansel that whenever marked hyperplasia and polyposis develop the membranes tend to become infected and invaded by bacteria. The neutrophilic response in the secretion in addition to the eosinophilic response is an indication of this infection. That bacteria may be present first in the mucous membrane and be the primary cause of the precipitation of an allergic condition is suggestive in some cases. He has observed cases in which the manifestations of allergy in the nose were precipitated by an acute upper respiratory infection of acute sinusitis yet these cases did not appear to be different from the other pure allergic types. Polyposis developed in some of these cases. A pure eosinophilic response in the secretions indicates an allergic process of an atopic nature and this reaction is maintained by the ordinary allergens. The

persistence of neutrophils in large numbers in addition to a certain number of eosinophils has, according to the author's experience, substantiated the belief of the existence of chronic infection. Repeated respiratory infections in cases of polyposis seem to play a part in increasing the edema, but the primary cause of polyposis appears to be allergic edema. In many cases in which there were repeated infections over a period of many years, polyposis has never occurred. There was no definite relationship between the onset of the nasal manifestations of allergy with acute infections of the upper respiratory tract and the eventual development of polyposis in the author's series of cases. In a proportion of cases of polyposis the nasal manifestations of allergy began primarily as hay fever or pollinosis.

**Castor Bean Dust Sensitization**—Bennett and Schwartz discuss the cases of two persons who acquired a sensitiveness to the dust of the castor bean, characterized by sneezing, coryza, itching of the eyes, cough, wheezing respiration, and in addition in the second case urticaria of the face, neck and hands. Exposure to castor bean dust caused allergic symptoms, while avoiding it afforded complete relief. Testing intracutaneously with castor bean dust extract in the following dilutions produced the following reactions: 1 100,000, 4-plus, 1 1,000,000, 4-plus, 1 10,000,000, 3-plus, 1 100,000, 3-plus, and the second patient gave a 3 plus reaction to a dilution of 1 1,000,000. Although other extracts of powerful allergens, such as horse dander, horse serum, rabbit epithelium, cottonseed, pollens and fish, are used in tests in high dilution, castor bean extract requires still higher dilutions for testing in order to avoid constitutional reactions.

**Cholesterol Content of Milk Constituents**—Ansbacher and Supplee found the cholesterol content of butter oil to vary between 0.24 and 0.34 per cent. The cholesterol content of butter oil is greatly reduced by heat in the presence of incorporated air. The study of the distribution of cholesterol in milk showed that about 18 per cent of the total cholesterol of milk is associated with the proteins. The butter fat carries a greater amount of cholesterol than any other milk constituent. When calculated to the dry basis, the lactalbumin has the next highest cholesterol content, which is several times greater than that of the other milk proteins. The cholesterol content of lactalbumin appears to be more uniform than that of other milk constituents. The fatty matter associated with the proteins of milk contains a relatively constant and uniform amount of cholesterol, which is many times greater than that of butter fat. Oxidation of butter oil by heat in the presence of incorporated air diminishes, or even completely destroys, the provitamin D. The cholesterol associated with the milk proteins contains matter that can be activated antirachitically. Lactalbumin after momentary periods of exposure to ultraviolet rays shows a substantial vitamin D potency. The fatty matter of milk, prosthetically bound with the proteins is indicated as being of possible significance in accounting for the clinical merits of irradiated milk.

**Bulbar Poliomyelitis and Its Treatment**—Smith and Fineberg present the clinical signs and symptoms of unilateral and bilateral paralysis of the palate in acute anterior bulbar poliomyelitis. Their experience with 1,325 cases of poliomyelitis, of which 29 per cent were bulbar, convinces them that lumbar puncture is unnecessary and definitely contraindicated in bulbar poliomyelitis in which paralysis is self evident. When the diagnosis is doubtful and a lumbar puncture is essential, a small amount of fluid should be withdrawn slowly, because when the subarachnoid pressure is suddenly released by lumbar puncture the pressure within the cord is similarly released. The spinal cord bulges instantly, the capillaries dilate and blood rushes into them. With the sudden onrush of blood, oozing takes place from the finer blood vessels and additional capillary ruptures in the bulb are liable to occur and in many instances probably do occur. When the bulb is the site of hemorrhage, edema results, the vital centers are strangulated and death is sure to follow. Lumbar puncture does not benefit the patient but subjects him to the danger of hemorrhage into the bulb. The use of the respirator is definitely contraindicated in these cases. It is indicated in intercostal, diaphragmatic and abdominal muscle paralysis, in which prolonged artificial respiration is required. Paralysis of the respiratory center, when and if it occurs, is part of the vasomotor collapse and a phase of the terminal picture. All drugs that depress the respiratory center are contraindicated. Atropine sulphate, when given in large doses, is a depressant of the respiratory center and therefore its repeated use is inadvisable. Patients who are unable to swallow because of partial or of complete palatine paralysis should be put to bed in a prone position on a hard mattress. Usually there is a marked flow of mucus from the mouth and nose. Most of the secretions are removed in this manner, but a considerable amount of the mucus may remain in the pharyngeal space and stagnate behind the posterior pillars. To diminish the possibility of aspiration pneumonia and catarrhal or purulent otitis media, suction should be instituted by gently introducing a suction catheter into the mouth and throat. From 3 to 4 ounces of tap water, at body temperature is introduced by rectum every four hours by means of a funnel and catheter during the first day. On the next day, in addition to this, hypodermoclyses of a 5 per cent solution of dextrose in physiologic solution of sodium chloride are started. Two daily hypodermoclyses and instillations of water by rectum are continued as long as nausea persists. The restlessness and nausea correspond to the period of elevated temperature. Nasal gavage is not begun until the elevation of temperature has subsided. The amount of fluid in the first gavage should not exceed 2 ounces. The amounts are gradually increased until a maximum of 8 ounces every four hours is reached. The gavage diet consists of 8 ounces of milk, 2 ounces of sugar and one egg. As soon as the palate begins to move the patient is

placed in a supine position without a pillow, and a semisolid diet is given. The head is then slowly elevated from day to day until the child is able to take nourishment without any difficulty.

**Copper and Iron in Treatment of Secondary Anemia**—Cason used copper and iron in the treatment of six children suffering from secondary anemia due to malnutrition or infections, whose hemoglobin varied from 40 to 74 per cent. They were given from 5 to 10 cc (according to their ages) of a solution containing 0.5 Gm of cupric sulphate and 10 Gm of ferric ammonium citrate per hundred cubic centimeters of 25 per cent solution of aromatic elixir (U. S. P.), three times a day. Six children whose secondary anemia was similar to that of the first group and whose hemoglobin on admission averaged 63 per cent were given cuprous and ferrous glutamate. This material was made up in capsules, each of which contained 30 mg of cuprous glutamate and 750 mg of ferrous glutamate. The dosage was three capsules daily. The hemoglobin content of these children was determined at intervals for an average of four weeks by the Sahli method and recorded on a percentage basis, 16 Gm of hemoglobin per hundred cubic centimeters of blood being regarded as 100 per cent. The children treated with the cupric and ferric compound and those given the cuprous and ferrous compound showed the same rate of increase in their hemoglobin content, 46 per cent each week.

**Bacillus Enteritidis Meningitis**—Vaughn reports a case of meningitis caused by *Bacillus enteritidis* of Gärtner in an infant, aged 15 months, in whom the colitis found at necropsy, with the history of diarrhea preceding the onset of meningeal symptoms suggests that the portal of entry of infection was the intestinal mucosa. The positive blood culture warrants the assumption that the meningeal involvement was metastatic through the blood stream. *Bacillus enteritidis* was found in the mastoid antrum although the tympanic membranes showed no evidence of middle ear infection during life.

**Dinitrophenol**—Tainter observed that rats in which metabolism was increased by the administration of dinitrophenol or thyroto were found to be more susceptible to lowered oxygen tensions in the respired air than were normal rats. For the same degree of metabolic stimulation, dinitrophenol had an effect on the sensitivity to oxygen lack similar to that of thyroto, hence dinitrophenol cannot serve in an oxygen sparing capacity in the intact organism. Inhalation of pure oxygen markedly reduced the toxicity of dinitrophenol for rats, as indicated by mortality curves. The administration of oxygen may therefore be of value as an antidote in cases of clinical overdosage with dinitrophenol. Dinitrophenol failed to cause its usual metabolic stimulation in rats, guinea pigs and pigeons kept at atmospheric temperatures of from 2 to 6 C., as indicated by oxygen consumption or body temperature changes,

and it caused fewer fatalities. This abolition of metabolic action was not due to impaired absorption of the drug from the subcutaneous tissues, since the same peculiarity was observed with intraperitoneal injections. The author discusses the various possible explanations of this phenomenon and suggests that, since low temperatures decrease the toxicity of dinitrophenol, the use of ice packs or other cold applications to the skin in addition to inhalation of oxygen is worthy of trial in cases of clinical poisoning or overdosage with the drug.

**Action of Acetylsalicylic Acid on Growing Bone**—Much performed experiments on rats in which relatively large doses of acetylsalicylic acid (equivalent on a per kilogram basis to ten times the maximal official British Pharmacopoeia dose) given daily for a month did not cause any decalcification of the bone as judged by roentgen translucency. Acetylsalicylic acid broadens the calcified zone in ossifying cartilage. This effect is due to the acetylsalicyl radical rather than to the acidic nature of the drug. The addition of calcium to the molecule to form the calcium salt protects young animals from the harmful action of the drug on growing bone. Calcium acetylsalicylic acid taken by mouth raises the proportion of calcium in the blood serum. Repeated slightly toxic doses of calcium acetylsalicylic acid interfere less with the growth of young rats than do equivalent amounts of acetylsalicylic acid itself.

**Pathologic Changes in Mastoids**—To visualize what takes place within the mastoid on successive days following the onset of acute suppurative otitis media Tibbets analyzed his observations in twenty five cases that came to operation. He observed that in acute mastoiditis marked pathologic changes may be present in the mastoid as early as the third

day following the onset of an acute suppurative otitis media. The rapidity of bone destruction depends to a great extent on the age of the patient, being more rapid in the young. In his series, four out of five complications occurred in patients having sclerotic mastoids. This type of mastoid can be detected roentgenologically and would seem to be an indication for early operation. Some patients with acute labyrinthitis, Gradenigo's syndrome and meningeal irritation may recover without other intervention than the simple mastoid operation. A sudden decrease or cessation of discharge from the middle ear, in the presence of a free opening in the drum and with an exacerbation of clinical symptoms, nearly always means complete blocking of the mastoid antrum, which can be relieved only by operation. In patients who continue to show signs of mastoid involvement as late as the eighteenth day following the onset of an acute suppurative otitis media, even without marked evidence of bone destruction, there exists a sufficient pathologic condition within the mastoid to make a satisfactory recovery without operation seem extremely doubtful.

**Division of Thyroid Arteries in Angina Pectoris**—In studying a group of patients from five to ten years after thyroidectomy had been performed on account of persistent or recurrent hyperthyroidism, Horgan and Lyon observed that the patients who had had a subtotal thyroidectomy with ligation of both superior and both inferior thyroid arteries did not show any evidence of hyperthyroidism and that the tachycardia or auricular fibrillation had ceased. They conclude that stopping the effects of hyperthyroidism was not entirely due to removal of the major portion of the thyroid, but that the division and ligation of the superior and inferior thyroid arteries cut the pathway of stimuli from the sympathetic nervous system to the thyroid and consequently prevented regeneration of the tissue that was allowed to remain, thus avoiding overactivity of the remaining tissue by stimulation. The effect of this operative procedure was also shown to lower the basal metabolic rate, to lower the circulatory demands and to lighten the work of the heart. Because the results of this operation had been so striking, the authors used a similar method in a case of congestive heart failure and angina pectoris that is, cutting off most of the blood supply and cutting the pathways of stimuli to the thyroid by dividing both superior and both inferior thyroid arteries at one operation. The patient has been relieved of anginal failure and has enjoyed relatively active life for four months.

**Leukoplakia Buccalis and Keratosis Labialis**—From a study of 520 cases of leukoplakia buccalis and keratosis labialis Sturgis and Lund believe that the lesions are definitely pre cancerous. Bad dental hygiene and the use of tobacco are both almost universal and equally important as etiologic factors in leukoplakia and keratosis of the mouth and lip. Syphilis is found in about 30 per cent of patients with leukoplakia of the tongue, but it is of minor importance in all other buccal locations of this lesion. In the series of cases studied, the location of the lesion appears to have no prognostic significance. Similarly, the duration of the lesion before treatment has apparently no definite bearing on the results of treatment. The size and extent of the lesion seem definitely to influence the prognosis on the basis of treatment received between 1918 and 1926 at the clinic of the Huntington Memorial Hospital. Extensive leukoplakias involving wide areas of the buccal mucous membrane do not respond well to irradiation. If the lesion persists after all the irritating factors are removed the patient must be kept under constant observation, and prompt electrosurgical excision should be done of any areas showing suggestive evidence of cancer.

- \*Symptoms Suggestive of Duodenal Ulcer Arising from Hookworm Infection J H Gibbes Columbia—p 102
- Diagnosis and Surgical Treatment of Malignant Lesions of the Large Bowel F W Rankin, Lexington Ky—p 110

**Symptoms in Hookworm Infection Suggestive of Duodenal Ulcer**—Gibbes states that the symptoms caused by parasitic fixation in the duodenum are not typical symptoms of ulcer. The patients have a hunger pain, but they do not have the pain with the unfailing, clocklike regularity of true ulcer. The pain seems to be located quite frequently in the left upper part of the abdomen. The sufferers from duodenal ulcer, irrespective of treatment, will classically become symptom free at intervals and go for months with "perfect digestion." In the patient having intestinal parasites the symptoms continue without such periods of relief. The true ulcer patient often puts his finger on a localized point of tenderness in the right upper part of the abdomen, while the intestinal parasite victim complains of much more diffuse tenderness. The physical examination yields almost nothing of exact differentiating value. The blood picture of an eosinophilia should always suggest the possibility of an intestinal parasite and is often the lead that elicits a correct diagnosis. The number of eosinophils varied in these diseases from 2 per cent to as high as 17 per cent in the author's series, though much higher counts have been reported. Careful examination of the feces gives the most positive information. The success of a search for eggs of parasites will depend to a marked degree on the suspicion of their presence. The roentgen observations of the stomach and duodenum are to some extent similar in duodenal ulcer and in parasitic disease of the intestinal tract. The stomach is irritable and tends to empty with abnormal rapidity in both conditions. The pylorus is spastic and the duodenal cap is abnormal. However in duodenal ulcer the duodenal deformity persists in spite of every effort to overcome it, while the duodenal deformity resulting from parasitic disease can be made to disappear under fluoroscopic manipulation. The back and forth, churning movement in the duodenum associated with hookworm disease and described by Henderson is an important diagnostic criterion.

**Staphylococcus Aureus Endocarditis with Recovery**—Baumgartner reports a case of bacterial endocarditis in which the chief complaint was high fever with a temperature following a chill ranging from 103 to 104 F daily for seventeen days, fulness in the chest and a healing carbuncle on the right buttock. Five days after admission, 3 grains (0.2 Gm) of sodium cacodylate was administered intravenously, and daily injections of from 7 to 7½ grains (0.45 to 0.48 Gm) of the drug were given subsequently. Sodium cacodylate was discontinued on the twentieth day. Following this therapy the temperature never exceeded 102 F and with one or two exceptions the peak of the daily temperature dropped several tenths of a degree each day until 98.6 F was reached. Three weeks later there was an increase of 22 pounds (10 Kg), the heart was apparently normal on examination and no pathologic change was detected in the knee. Two weeks later the leukocyte count was 8800, the patient was again having trouble with the right knee and was placed on crutches. A blood culture made two weeks later was negative for any growth after an incubation period of one week. The patient has been examined at frequent intervals since with no evidence of recurrence of his trouble. One and one-half years after his illness there has been a gain in weight of 40 pounds (18 Kg) and the only cardiac abnormality demonstrated by physical examination is a faint presystolic murmur.

# Epidemic Papulopustular Eruption in Coal Miners

Dowling and Brain discuss an epidemic causing papulopustular eruptions, which occurred recently among colliers working in a Kent coal mine. There were no constitutional symptoms. A man who was in otherwise normal health experienced an irritation while at work and developed a widespread eruption of more or less constant distribution within a few hours. This eruption became more widespread and more irritable during the succeeding few days, whether the man remained at work or not, and then if he ceased work began to die down spontaneously. With one exception in the case of those who remained at work no remission took place, and most of those who returned to work before the eruption had cleared up promptly relapsed. Some of those who recovered have since relapsed on returning to work. The eruption consisted of closely set punctate lesions involving in every case the extensor aspects of the thighs, knees, legs, buttocks and forearms and in many cases the flexural aspects of the forearms, the waist line, the chest and the back. In almost every case the eruption was most dense on the hairy part of the thighs, knees, buttocks and forearms. The lesions consisted of discrete papules, some were almost flat, many were scaly, and a certain proportion were capped by a small crust or pustule. In patients having rather dry skins the eruption consisted of flat, dry scaly spots of eczematous type, either discrete or aggregated into irregular patches. On the nonhairy parts of the skin, such as the abdomen, chest and back, the lesions were usually small dry papules, rather like those of the follicular variety of seborrheic eczema. A biopsy examined serially showed one of the lesions to consist of a superficial staphylococcal pustule with its subcorneal colony of organisms. Direct smears and cultures from the pustules revealed the presence of *Staphylococcus albus* and occasionally *aureus*. The etiologic problem appears to have three possible solutions: (1) The atmospheric conditions prevailing in the mine at the time were noxious to the miners' skins, perhaps because the mine was closed for a few days, (2) there was some new irritating property in the coal dust which, in combination with intense sweating was capable of producing an irritant folliculitis, and (3) the condition might be due to infection in the mine with some fungus or organism.

# Tribrom-Ethanol Narcosis in Operations for Goiter

In employing tribrom-ethanol narcosis in toxic goiter operations, Keynes gave the patients one-eighth grain (0.008 Gm) two hours before and one twelfth grain (0.005 Gm) of morphine one hour before operation. Forty-five minutes before operation the patient is given 0.09 or 0.1 Gm of tribrom-ethanol solution per kilogram of body weight by rectum. The larger amount is given to the more acutely toxic patients. All the patients have been unconscious when brought to the oper-

ating table except one, who was suffering from diarrhea and was unable to retain more than a fraction of the dose. When the patient has been placed on the operating table, the mask for the administration of gas and oxygen is fixed in position, but as a rule no gas is given at this stage. The operative area is infiltrated with a 0.5 per cent solution of procaine hydrochloride in physiologic solution of sodium chloride containing 1:500,000 of epinephrine hydrochloride. The infiltration is effected rapidly with a Dunn self filling syringe. The volume of solution used is usually from 100 to 150 cc. For some of the more mildly toxic patients this combination of basal narcosis and local infiltration with procaine hydrochloride is all that is needed, but in fewer than 10 per cent is the operation completed without any gas and oxygen being given. Once the patient has been roused, gas and oxygen is begun at once. Perfect anesthesia can be maintained with a minimal amount of gas, and cyanosis can be avoided entirely. When the patient is back in bed, he usually remains quiescent for two hours or more, so that mental disturbance is eliminated at this stage as effectually as before. Under tribrom ethanol narcosis the pulse rate may rise a little with the initial disturbance and the induction with gas and oxygen, but not infrequently the pulse rate is actually lower at the conclusion of the operation than at the beginning. There is seldom any alarming rise of pulse rate during the operation. Of the author's 220 patients who have been operated on under tribrom ethanol narcosis, only three died soon afterward. One of these was a woman of 24, who was acutely ill. Of the other two patients, one had gross auricular fibrillation and died from heart failure a few hours after the operation. The other was so ill that she developed an acute thyroid crisis a few hours after the ligation of one superior thyroid artery and died.

**Electrocardiographic Changes in Angina Pectoris**—Gray presents four cases of angina pectoris having a brief attack in the consulting room. The attacks were probably induced by excitement, as there was no preceding exertion, and were relieved by rest, the longest time for complete cessation of pain having been twenty minutes. Definite changes in the ventricular complexes of the electrocardiograms were demonstrated. These changes resembled those produced by coronary thrombosis. They are not always present owing no doubt to 'silent areas' in the myocardium changes that do not affect the electrocardiogram. The author states that the positive evidence adduced in the foregoing cases and in those previously reported points toward the coronary origin of anginal pain.

**Human Gnathostomiasis**—Proinmas and Daengsvang add nine cases of human gnathostomiasis to the twelve cases reported previously. They have seen twenty cases clinically diagnosed as gnathostome infestation one of which was confirmed by extraction of a worm by the patient from the buccal mucosa after suffering from facial swelling for about one week, but unfortunately the patient had thrown the worm away. The disease is apparently confined to oriental countries and is especially common in Siam. It occurs in both sexes at any age (20 to 57 years). The disease is characterized by a migrating intermittent swelling of varying size which is usually

painless, but on certain occasions is more or less itchy and painful. Pain, if present, is boring or biting in character and in rare cases is severe enough to disturb sleep. The swellings did not show pitting on pressure and underwent suppuration in two cases only, probably on account of secondary infection. The regional lymph nodes are not involved, unless there is added bacterial infection. There is no definite anatomic distribution of the lesions, they are found on the abdominal wall, chest, shoulders, face, hands and feet. In one instance the parasite simulated mastoiditis (Datta and Maplestone, 1930), and in one of the authors' cases it presumably pierced through the tracheal wall, producing hemoptysis. As a rule the blood picture shows eosinophilia of varying degree, but this is not a pathognomonic feature, since it occurs in many other tropical diseases. Though nothing is known with certainty regarding the mode of infection and transmission of the parasite, recently the authors (1933) discovered the development of its larval form in a cyclops and are carrying on experiments. Of the many methods of treatment tried, none apparently surpass surgical intervention.

- Recent Advances in the Treatment of Carcinoma of the Esophagus from the Surgical Aspect G Turner —p 297  
\*Carcinoma of the Esophagus Treated by Radiation F J Clemmison and J P Monkhouse —p 313  
\*Further Observations on the Sphenopalatine Ganglion D Stewart and V Lamberti —p 319

**Carcinoma of the Esophagus Treated by Radiation**—Clemmison and Monkhouse treated eighty-nine cases of carcinoma of the esophagus with radiation but the results were so disappointing that they wonder whether it is not actually harmful to treat these patients by the application of radon to the center of the growth and whether they might not live longer if their only treatment was a preliminary removal of all teeth followed by a gastrostomy. These patients do not seek advice until peripheral extension and early metastasis have made it impossible for radiation to reach the outlying parts of the growth with destructive strength. The suspicion arises that there may even be a certain danger of stimulation of the rate of growth at the periphery and that thus the end may be hastened rather than delayed. The average period of survival for the whole series was 5.6 months (for growths in the upper part 6.7 months, in the middle part 5.4 months and in the lower part 6.9 months). For the ten women it was 8.5 and for the seventy-nine men it was 5.2 months. The relation of history to the survival period suggests that a short history does not necessarily indicate that the case is more recent in the sense of being less advanced and so more amenable to treatment than one in which the history is longer. This suggestion is confirmed by a study of the survival times of patients grouped according to length of history.

**Observations on the Sphenopalatine Ganglion**—Stewart and Lambert state that cocaineization of the foramen is a quick and efficient method of producing temporary anesthesia of the nasal cavity. Afferent impulses from local lesions in the superior division of the fifth nerve may be blocked by a local

application to the sphenoplatine foramen. As a result of this, painful conditions in this region which produce referred pains at a distance can be controlled. The latter fact accounts for the control thus exercised over the pains in the ear, neck and shoulder. As the afferent path of the nasopulmonary reflex demonstrated by Brodie and Dixon is abolished by cocainization in this region, it is reasonable to expect that certain cases of reflex spasmodic asthma will be controlled in the paroxysms. The authors cannot find any evidence to support the view that there are afferent sympathetic fibers present in the nerves.

**Therapeutic Action of Prostigmine**—Carmichael and his associates observed the action of dimethyl carbamic ester of 3 oxyphenyl-trimethyl-ammonium-methyl sulphate (prostigmine) in forty-one patients. It was administered by subcutaneous or intramuscular injection of the solution provided in ampules by the manufacturers. Thirteen of the patients were selected from among ordinary hospital patients, because they presented no special lesion of the digestive tract that would interfere with observations on the action of the drug under approximately normal conditions. In twenty-eight instances, patients were selected because the action claimed was desired, and in sixteen of these postoperative intestinal distention was present. It was observed that the subcutaneous or intramuscular injection of the drug produces active movements (contractions and relaxations) in the colon in normal subjects, but there is no evidence that these movements are such as to produce the forward passage of the contents of the colon. Considerable variation was seen in the intensity of the response to different subjects. The drug appears to be free from side actions on the rate of the heart and blood pressure when given in doses at least double the recommended dose. In from ten to twenty minutes following its injection, abdominal pains and rumblings occur in cases of gaseous distention of the intestine and these go on for almost thirty minutes. It is necessary to give an enema to get a satisfactory passage of flatus. The authors suggest that the drug followed by solution of pituitary and then an enema, may be an effective measure for stimulating peristalsis in postoperative distention.

**Acute Perforation of Peptic Ulcers**—The observations of James and Matheson of seventy-five cases of perforated gastric and duodenal ulcers revealed that subphrenic and pelvic abscesses are the result of delay. Intestinal obstruction has been encountered on two occasions and occurred round the site of the drainage tube necessitated by gross peritoneal soiling. The occurrence of hemorrhage from a second ulcer led to a fatal termination in two cases on the tenth and twenty-fourth postoperative days respectively. In each case the perforation had occurred in the duodenum, and the bleeding was shown at necropsy to have its origin in an unsuspected gastric ulcer—in one case eroding the splenic artery. The possibility of this occurrence indicates the desirability of searching for other ulcers at the time of operation and stresses the need for prolonged and thorough after-treatment. It is often stated that bleeding ulcers do not perforate and that perforating ulcers do not bleed but the authors have seen this association in two cases. In one the perforation followed immediately on a hematemesis and in another profuse bleeding occurred from an ulcer high on the lesser curve which had been sutured ten days before.

**Massive Diffuse Hypertrophy of Breasts in Girls**—Wakeley reports four cases of hypertrophy of the breasts and states that, although numerous partial amputations have been advocated from time to time such operations should be condemned as they leave behind a mass of pathologic material which is later a source of trouble to the patient. To attempt transplantation of the enlarged and attenuated nipple to the upper part of the breast has nothing to recommend it, for the nipple is so stretched and flattened that it has lost all its contractile tissue. If the hypertrophy was a simple overgrowth of the fat and fibrous stroma without any alteration of the glandular tissue, a partial removal might be considered. This, however is not the case, as the gland substance participates in the hypertrophy and sometimes adenomas are found as well. These conditions seem to justify the removal of the whole of these useless, functionless and frequently painful breasts. The best method of removing the breasts is by transverse elliptic incisions, which are united to form a transverse scar. Bleeding can be controlled by making the upper part of the elliptic incision first. The main vessels are exposed and clamped, and when the lower part of the incision is made there is practically no bleeding. Shock is not encountered if the bleeding is minimal during the operation. Transverse wounds over the chest heal well and are not subject to keloid formation. The etiology of diffuse hypertrophy of the breasts in girls remains obscure, but there is probably some upset in the endocrine balance, as shown in the change of the clinical picture after their removal. The condition is in no way like a true elephantiasis.

**Nasal Treatment of Hay Fever**—Francis describes a treatment of hay fever by light intranasal cauterization. The procedure is as follows. A small swab of absorbent cotton is twisted on the end of a probe, dipped in a 10 per cent solution of cocaine hydrochloride and wrung out almost dry. The interior of the nose is examined, and the septum and the inferior and middle turbinates are touched lightly in rotation with the swab. The most sensitive areas are anesthetized by painting them three or four times with the solution. The areas should be touched lightly with a fine cauterizing point heated to a dull red, the heat being turned off just before the cauterizing point is applied. One or more light longitudinal burns should be made, when necessary, on the septum and inferior turbinate, and a few light touches on the anterior edge of the middle turbinate. The marks produced by the cauterizing should be nearly or entirely gone in a week or ten days. If necessary a second application is made to any remaining hypersensitive areas. There is no pain, swelling of the parts or sloughing, and no after-treatment is required. Of the author's 100 patients treated in this way, seventy-four patients obtained complete or great relief, moderate relief was evident in twenty-two and four patients obtained either slight relief or none.

 \*Significance of Testing for Carbohydrates Especially Galactose in  
 Functional Examination of Liver I Pavel I Florian and I Rad  
 van—p 380

**Carbohydrates in Functional Examination of Liver**—Pavel and his collaborators studied seventeen patients having benign infectious jaundice to decide whether the insufficient galactose utilization of the liver is not due in part to insufficient insulin secretion. They attempted to observe the influence of insulin administration on galactose elimination in cases of catarrhal jaundice with positive galactosuria. In three cases studied they found the galactosuria influenced by insulin. The apparent deficiency of the insulin producing apparatus of the pancreas in catarrhal jaundice was corroborated by the insulin resistance of these patients. They also examined the condition of the pancreas in seventeen cases of infectious jaundice by measuring the lipase activity of the pancreatic secretion produced by milk and by measuring the urinary diastase. In fifteen of the seventeen cases they found a functional deficiency of the pancreas. This series of cases showed clinically similar syndromes but the cause was certainly not constant. Eleven patients had hypertrophic cirrhosis and six an atrophic cirrhosis. In nine of the eleven cases of hypertrophic cirrhosis the authors studied the lipase activity of the secretion produced by the pancreatic substance, and the urinary diastase. In two cases they observed the urinary diastase alone. In the group of nine cases they found the two tests of pancreatic insufficiency positive five times. In the second group of two cases they found an increase of urinary diastase once which corresponded to a pancreatic edema confirmed by necropsy. In the other observations the urinary diastase was diminished. A parallelism existed: alimentary glycosuria was positive in the cases in which the pancreatic tests were positive and galactosuria was negative when pancreatic tests had been found normal and anatomic examinations confirmed the integrity of the pancreas. Less definite were the observations in the six cases of atrophic cirrhosis. In one case the two tests were positive, in two a single test (duodenal lipase) was positive, and in three the tests were normal. Thus the results of clinical research seem to show that the functional state of the pancreatic external secretion is almost constantly affected in catarrhal jaundice, and often in the cirrhotoses.

 \*Periduodenitis of Appendicular Origin Clinical and Roentgenologic Diagnosis S Kadrnka and P Bardet—p 354  
 \*Argentaffine Tumors of Appendix P Topa E C Craciun and D Caramzulescu—p 392

**Periduodenitis of Appendicular Origin**—Kadrnka and Bardet found that periduodenitis of appendicular origin is more frequent than usually supposed. It is more frequent, in fact, than postcalculous or postulcerous periduodenitis and is generally found in young adults. So-called essential periduodenitis must be considered only after the exclusion of disorders both near and far and especially appendicitis, even when apparently clinically cured. In such instances histologic evidence of the remains of an old appendicitis is necessary. Periduodenitis of appendicular origin generally involves the proximal part of the first portion of the duodenum and by choice the lesser curvature of the bulb. It is also frequently localized at the level of the third part in the region of the neck of the mesentery, thus producing a mesocolic form which is characterized by a non-reducible stenosis. In practice appendicular periduodenitis forms two groups that in which the dyspepsia is accompanied by the appendicular syndrome and that in which it is not. In the first form roentgenography is largely responsible for the pathologic diagnosis. In the second group clinical diagnosis is especially difficult. The authors feel that treatment should be directed both toward operative freeing of the duodenal adhesions and removing of the primary focus i. e. the appendix.

Although good results sometimes follow appendectomy alone, a second operation is often necessary, and it seems desirable to perform the two procedures at the same time rather than run the risk of a second operation. They conclude that in view of the numerous early and late complications of appendicitis it is wise to remove this organ at the first sign of involvement and even better to remove a normal appendix than chance the complications of which periduodenitis is only one.

**Argentaffine Tumors of Appendix**—Two cases of primary tumor of the appendix are reported by Topa and his collaborators. In both instances the histologic arrangement of the cells of the stroma was more similar to that of a trabecular stomach cancer than to that of a benign process. In both instances there was an affinity of the tumor tissue for ammoniacal silver. The authors believe that appendicular neoplasms are practically always a complication of chronic inflammation. It is apparently justifiable to admit three kinds of epithelial cancer of the appendix. The first is the argentaffine epithelioma derived from the so called Kulchitsky-Schmidt-Ciaccio cells. The second group is the simple epithelioma developed from the cells common to the epithelial lining and glandular crypts. Finally there is the mucocoele (a benign tumor) which may develop from the muciparous cells. In the particular tumors cited in this paper diagnosis as to malignancy is difficult. The histologic structure and argentaffine nature of the tumors favor an attenuated cancer while the extreme rarity of postoperative recurrence is in favor of their benign nature.

 Dental Manifestations of Hereditary Syphilis Vais—p 868  
 Placental Retention Case J Volpert—p 876

**Postinfluenzal Adenopathies of Infancy**—Ruelle discusses a group of children who develop tracheobronchial adenopathy subsequent to grip. He concludes that a lulu syndrome of nontuberculous nature exists which occurs after numerous infections, such as measles, whooping cough, syphilis and influenza. The principal cause appears to be a rhinopharyngitis. This condition has a double pathologic effect. It plays a mechanical part in narrowing the upper respiratory passages and creates a respiratory insufficiency. It plays also an infectious part by means of the mucopus either nearby or at a distance. It is not safe to diagnose tuberculosis lightly in the face of a continued fever. One cannot ignore the bad effects of rhinopharyngitis. If the latter is acute it is easily recognized, if subacute, it may create a fever lasting weeks or months or with episodes of fever for several months. This type of adenopathy serves as one of the therapeutic triumphs of arsenic. Iodides and sometimes sulphur are valuable accessories. A final sojourn at the seashore completes the results obtained by medicaments. If this is impossible, ultraviolet rays are helpful.

 Growth of Connective and Osseous Tissue Cultivated in Vitro in Presence of Certain Metals Biologic Study of Osteosynthesis G Menegaux P Moysse and D Odette—p 658

**Esophageal Sequelae of War Gassing**—Worms and Leroux-Robert illustrate by cases several forms of esophageal involvement resulting from gas intoxication. In one case there was enormous esophageal dilatation which took only twelve or fourteen months to develop. In another, in spite of only mild cardiac stenosis ectasia of the esophagus existed thus showing the accessory nature of cardiospasm. In a third case massive dilatation of the esophagus existed in the absence of any stenosis of the cardia. Two other patients showed marked cardiac stenosis with gradual dilation. The authors believe

that these observations suggest that the dilatation is the primary phenomenon and that the stenosis plays only a secondary role in its development. They are inclined to attribute the primary ectasia to a toxic change of the parietal nervous system. The toxin has an elective action on the nervous system and can determine at what level of the esophagus dilatation will occur. Thus stenosis of the cardia of toxic, infectious, or inflammatory origin can produce esophageal dilatation due to the weakened wall, but this stenosis, while common, is a secondary phenomenon, inconstant, and not absolutely necessary to the development of the ectasia.

**Infundibulo Tuberian Syndrome**—Lhermitte and Pagniez describe the case of a woman who in infancy had had poliomyelitis and an encephalitis of indeterminate nature. At the age of 40, a facial paralysis with crossed hemiplegia appeared, followed two years later by a diabetic syndrome (polyuria, polydipsia, glycosuria and hyperglycemia) with an increase of obesity, menstrual difficulties and epileptiform attacks. The roentgenogram showing enlargement of the sella turcica added to the impression that the cause was a hypophyseal lesion. This hypothesis was proved false by anatomic studies which were made possible by the development of a fatal apoplexy. The hypophysis and sella turcica were entirely normal while the hypothalamic center appeared grossly altered by an infectious process. Not only did the basal leptomeninges show a dilatation of the vessels but the walls of the vessels were also infiltrated by lymphocytes and plasma cells. The quality and intensity of the process became more evident when the region from the terminal lamina to the peduncle was examined. From a topographic point of view this cellular infiltration developed in an elective manner from the terminal lamina to the peduncle but, although it was marked deeply in the gray substance, it was practically completely absent in the white substance. In the latter, some vessels surrounded by a collar of mononuclear cells were the only changes. It is apparent from this case that the differentiation of some conditions, which seem to be of hypophyseal origin, from morbid processes of the infundibulo tuber cereum region is difficult but should be attempted.

\*Cutaneous Reaction with Diphtheria Toxin. Attempt at Simplification of Schick Test. T. Reh—p. 513  
Liver and Chronic Rheumatism. Vichy Cure. P. Vauthey and M. Vauthey—p. 514

**Sour and Dry Milks in Feeding of Nurslings**—Feer says that research has revealed that the addition of organic acids, such as lactic and citric acid, to cows' milk makes up largely for its disadvantages compared to human milk. He considers buttermilk the most valuable of the sour milks in the feeding of nurslings. It is particularly useful in feeding premature infants and infants with dyspepsia and fat intolerance. Excessive acidification may cause diarrhea. The low fat content makes buttermilk alone unsuitable for long periods but additions of butter, flour and sugar compensate for this. In evaluating lactic acid whole milk, the author states that it is valuable in the so-called two-milk nutrition. In nurslings aged 4 weeks it can already be used to supply two thirds of the food requirements in addition to one third of human milk and eventually it even may be given as the only food. Since this milk has a high food value, the mother must be told not to exceed the prescribed quantities. In acute toxic dyspepsia lactic acid whole milk is inadvisable, at least in the beginning stage. In the treatment of enteritis and dysentery lactic acid whole milk is of great value having an almost specific effect. It has proved of great aid in dystrophy, atrophy, pyloric stenosis whenever there is a lack of appetite and in many infectious diseases. Citric acid whole milk may be used in the same manner as lactic acid whole milk. Other sour milks evaluated by the author are protein milk, yoghurt and kefir. He considers the dry milks good substitutes for fresh milk when it is difficult to obtain. The fat-containing dry milks

are helpful in preparing concentrated foods. If dry milks have to be used for longer periods it is necessary to guard against vitamin deficiency by giving fresh fruit juices.

**Simplification of Schick Test**—For years Reh has made efforts to simplify the Schick test and to develop a cutaneous reaction with diphtheria toxin. His first experiments, in which he employed the usual toxin, failed. However, Ramon produced toxins with high antigenic value with which Reh has perfected a technique that permitted a "purification" of the Schick test. Following experiments on guinea-pigs he tried it on children. The toxin was obtained from the Pasteur Institute and it was always controlled pure and diluted, heated and unheated for its cutaneous activity on guinea-pigs. Two intracutaneous injections are made into one arm and to one is applied heated toxin and to the other one unheated toxin. On the other arm a control Schick test is made. The cutaneous reaction appears, as a rule, after forty-eight hours and attains its maximum between the second and fourth days. It does not cause local pain or general reaction. Its intensity is variable just as in the Pirquet reaction. On the basis of observations made in ninety-six cases the author concludes that, with rare exceptions, the cutaneous reaction gives the same results as the Schick reaction. The technique is simple by means of a vaccinostyle two scarifications are made on the forearm and on one of them a drop of toxin with 30 units of antigen is applied with a glass rod or with a drop-bottle and allowed to dry.

High Ileac Retrograde Invagination Resulting from Tumor in Child. A. Cioffi—p. 612

**Exfoliative Arsphenamine Dermatitis**—Zolezzi describes two cases presenting exfoliative dermatitis due to arsphenamine. He found a deficiency in the hepatic function of both patients. He emphasizes the importance of the functional activity of the liver in the course of arsphenamine treatment. The relation of grave cutaneous manifestations to the condition of the liver may in some cases be established by clinical examination, in others only by functional examination of the organ. The two patients responded well to intramuscular injections of various liver extracts. These extracts overcome the effect of the hepatic deficiency, in the absence of which arsphenamine dermatitis does not occur.

**Lactic Acid Content of Blood in Chronic Malaria**—Demurtas states that the lactic acid content of the blood of normal persons fluctuates between 11 and 14 mg. per hundred cubic centimeters. In studying eleven patients presenting chronic malaria, he found that the rate of lactic acid shows a marked and constant increase. Many investigators attribute this increase to symptoms of autophagia or to an abnormal passage of portal blood through the liver into the hepatic vein. The author maintains, however, that this lacticemia indicates a deviation in the function of the liver. It is his belief that an abnormal quantity of lactic acid is thrown into the circulation because the specific synthetic action of the liver is lacking owing to some alteration of the hepatic cells. Malarial infection always produces alterations of the hepatic parenchyma, such as fatty degeneration, pigment infiltration and necrosis of the cells. These alterations are not always demonstrable by clinical examination or laboratory investigation but they are by a systematic study of the lac-

ticemia. The change in function may be demonstrated many years after disappearance of the febrile attacks, of evolutive manifestations and of progressing malarial infection.

New Method for Roentgen Examination of Liver and Spleen P. Beltrín de Heredia—p. 482

**Ovarian Hypofunction in Etiology of Diabetes**—Arias Vallejo says that of all endocrine glands which, associated with insular lesions of the pancreas, take part in the development of diabetes, the ovary has the most important etiologic role. Of the diabetic women observed by the author, 86 per cent had ovarian hypofunction. Diabetes originated from a pathologic ovarian insufficiency, surgical ablation of one or both ovaries or roentgen castration (15 per cent). Light of the patients were vagotonic. The injection of an extract of total ovary or of pilocarpine chloride produced a decrease in the glycemia, marked within an hour after the injection, but followed by a return to the initial values about an hour and a half after the injection. The results obtained by the author indicate that glycemia decreases under the influence of insulin secretion produced by stimulation of the parasympathetic by the ovarian hormones. They also show the advantages of giving ovarian treatments to diabetic patients whose diabetes follows insufficiency of the genito-endocrine glands.

Prevention of Venereal Diseases E. Faro—p. 276

Abnormal Left Ureter and Urinary Incontinence M. Conde—p. 303

**Kala-Azar Coexisting with Malaria**—Cordeiro Ferreira reports a case of infantile kala-azar coexisting with malaria, which is extremely rare. Kala-azar and malaria, when associated in the same patient, do not exercise any reciprocal influence on each other. The patient shows clinical and hematologic symptoms of both infections. The malarial parasites are found in the peripheral blood of these children. The diagnosis of the coexisting kala-azar can be made only by means of the parasitologic examination of the blood of the spleen obtained by puncture. Reports have appeared in the literature with the statement that quinine treatment produces a harmful effect on kala-azar. In the author's case quinine produced a cure of malaria without aggravating the coexisting kala-azar, which in turn followed a favorable evolution to recovery when the patient was treated with an antimony preparation. In the author's case the splenomegaly disappeared slowly after the hematologic cure of the infection, as happens in all cases of kala-azar.

Advantages and Disadvantages of Therapeutic Use of Garlic During Childhood with Especial Consideration of Celiac Disease E. Mayerhofer—p. 106

**Etiology of Dysentery in Nurslings**—Teveli succeeded in demonstrating a bacillus of the dysentery group in forty-six out of fifty nurslings with primary purulent and sanguineous enteritis, that is in 92 per cent. These bacteriologic investigations prove the assumption, which so far has been based only on epidemiologic observations, that all forms of colitis and enteritis in which the stools are mucopurulent or sanguineous and purulent, and in which influenza, typhoid and paratyphoid can be ruled out, may be considered bacillary dysentery. The author thinks that the role of intestinal streptococci and of coli, Proteus or pyocyaneus bacilli is doubtful.

**Elimination of Chloride in Acute Hepatitis in Nurslings**—Török and Neufeld studied an epidemic of hepatitis in

a group of children. They conclude that the determination of the sodium chloride content of the urine, at least during childhood, is unsuitable for the detection of a hepatic lesion, because in acute hepatitis the chloride elimination is just as much dependent on the chloride content of the food as is the case in normal children. Observations by other investigators indicate that the infant is capable of storing only slight quantities of sodium chloride. It appears that in some pathologic conditions in which the chloride retention of the tissues is increased in adults the infant maintains its characteristic low chloride retention capacity. The authors think that this difference may be due to hormone factors.

State of Circulation in Collapsed and Normal Lung H. May—p. 341

**Shock, Collapse and Electrosurgery**—Schorcher defines shock as a clinical state resulting from a sudden trauma of the nervous elements influencing the central nervous system by way of the reflex arc. It is accompanied by a rise in the blood pressure, followed later by a fall. Collapse, on the other hand, while clinically similar to shock, differs from it causally in that it is the result of a chemical action. It is caused by the absorption of toxic substances and their effect primarily on the circulatory system. It is slower in development and is characterized by a primary fall in the blood pressure. The author conducted studies of the circulation in rabbits and dogs in a state of experimental shock. Shock was induced by traumatization of the skin and the muscles, by trauma of the nerves and the vessels of the peritoneum and by procedures on the spinal cord and the internal viscera, especially the kidneys, the testicles and the uterus. He found that the circulatory system did not always react in the same manner. Not infrequently the fall in the blood pressure and the slowing of the pulse preceded the rise in the blood pressure and the acceleration of the pulse. As a rule, however, the fall in the blood pressure was secondary to an initial rise. The blood pressure fell, as a rule, in abdominal operations. The same experiments were performed in rabbits in which both hemispheres were removed as well as in animals in which the spinal cord was severed at the level of the neck. The effect was identical. The severing of both vagi did not change the effect. When the area to be traumatized was anesthetized by infiltration, no shock or any evidence of circulatory disturbance was noted. The author further found that trauma of an electrosurgical procedure produced less shock than that produced by ordinary mechanical means. In his studies on collapse the author showed that the so-called rapid toxins of the defibrinated blood are not identical with adenosinphosphoric acid of the muscle because the latter does not lose its effect when boiled, while the former loses its toxicity when heated to 59°C. He further found that in contradistinction to the juice of a fresh muscle, that obtained from an electrocoagulated muscle did not cause death when injected into the ear vein of a rabbit. It is possible that the rapidly working toxins affect the lesser circulation and the splanchnic area first and the central nervous system secondarily. Electrocoagulation destroys the toxicity of the rapidly working toxins because it generates a temperature of from 60 to 80 degrees, whereas their activity is inhibited at 59 degrees of heat. The autolysates of expressed muscle juice when injected into the ear vein of a rabbit caused death in smaller doses than that of the rapidly working toxins. The author found that autolysates from an electrocoagulated muscle were less toxic. Comparative studies of growth of bacteria (Staphylococcus pyogenes aureus) on raw, boiled and electrocoagulated muscle showed that they grew more slowly and in smaller numbers on the electrocoagulated muscle. The author believes that he demonstrated in experiments that electrosurgical trauma produces little reaction on the part of the nervous and circulatory systems.

Whooping Cough and Tuberculosis E Gabriel—p 281  
\*Diastase in Cerebrospinal Fluid in Poliomyelitis F Eckardt—p 303

**Diastase in Cerebrospinal Fluid in Poliomyelitis**—Studies on the behavior of diastase in the cerebrospinal fluid of patients with poliomyelitis revealed to Eckardt that the inflammatory processes which develop in the central nervous system of these patients cause an increase in the diastase content of the cerebrospinal fluid. In the severe cases the diastase content generally exceeds 50 mg per hundred cubic centimeters, while in the mild cases the values are usually near the upper limits of the normal content namely, around 50 mg per hundred cubic centimeters. The comparatively slight increase in cells, together with a great increase in the diastase content, proves that the diastase, independent of the number of cells increases only under the stimulus of inflammatory processes in the central nervous system. With the improvement of the clinical symptoms, that is, presumably with the retrogression of the inflammatory processes in the central nervous system the erstwhile increased diastase values decrease again. A relationship between the sugar and diastase values of the cerebrospinal fluid could not be detected in patients with poliomyelitis.

\*Influence of Heparin on Epinephrine Permeability of Erythrocytes M Kuczarow—p 734

**Influence of Vitamins on Catalase Content of Blood**—According to Jusatz, the decomposition of hydrogen dioxide by the blood is a highly sensitive reaction. The clinicodiagnostic significance of this reaction, however, has been given little attention. The author found that the catalase capacity of the blood could be employed for the experimental demonstration of the action of vitamins on the animal organism. The low catalase content in avitaminosis could be corroborated on rabbits, which for several months received practically no vitamins. The later addition to vitamin B and D to their diet produced a considerable increase in the blood catalase. The author further studied the effect of provitamin A (carotene), of vitamin A preparations and of vitamin C (ascorbic acid). He found that feeding with carrots (provitamin A) as well as the addition of vitamin A to the diet exerted no influence on the catalase content of the blood of rabbits that received an otherwise vitamin deficient diet. Vitamin C, however, administered in the form of ascorbic acid, either intravenously or orally, produced an increase in the catalase content of the blood.

**Influence of Heparin on Epinephrine Permeability of Erythrocytes**—Kuczarow shows that heparin reduces the absorption capacity of the erythrocytes for epinephrine. He thinks that this condition can be explained by changes in the permeability of the erythrocytes which develop under the influence of heparin. This assumption is explained also by the retardations in the hemolysis, which, as is well known, are a result of the changes developing on the surface of the erythrocytes and further by the observation that foreign erythrocytes, which are laden with epinephrine and heparin cause no increase in blood pressure after their injection into the blood stream. The latter observation may be the result of (1) an inhibition of the hemolysis of the heparinized foreign erythrocytes (2) a reduction of the epinephrine absorption by the heparinized erythrocytes and (3) changes of the epinephrine action under the influence of heparin. The clarification of these factors requires further research.

**Physiologic Dose of Follicle Hormone**—In discussing the action of the follicle hormone, Schoeller points out that the synthetically obtained ester, such as the benzoate of the follicle hormone, is more effective than the crystalline follicle hormone. But organic chemistry has improved the follicle hormone preparation still more. In the course of hydrogenization experiments it proved possible to hydrogenize only the carbonyl group and not the first aromatic ring. The dihydro follicle hormone obtained in this manner is no longer an oxyketone, like the hormone, but rather a dioxy compound. However, this addition of two hydrogen atoms increased the efficacy of the hormone about five times and the dihydro follicle hormone is the most potent estrogenic substance. It was found that, in cases of ovarian insufficiency, from 200,000 to 300,000 mouse units of this hormone preparation had to be administered in the course of twenty days in order to produce the proliferation phase, and this may therefore be considered the physiologic dose. However, this number of units applies only to the preparation mentioned. The international unit agreed on in London in 1933 is 0.1 microgram (0.0001 mg) of the keto-hydroxy form of the hormone in pure crystalline condition. The fact that this unit has only one fifth of the potency of the unit mentioned brings the physiologic dose expressed in the international unit up to from one to one and one-half million units.

**Anterior Lobe of Hypophysis and Male Gonad**—On the basis of his own experiences, Neumann reaches the conclusion that the hormones of the anterior lobe of the hypophysis which are extracted from pregnancy urine cannot be considered maturation hormones of the male gonad, that is, it could not be proved that they lack sex specificity. The results of other investigators support this observation. It proved impossible to influence the genitalia of hypophysectomized male rats by estrogenic substance extracted from pregnancy urine, but this was possible by means of anterior hypophyseal hormone extracted from the gland. Since gland implants and gland extracts do not produce the same results, it will be necessary to use different methods in future researches and the entirely unproved assertion of the lack of sexual specificity of the hormones of the anterior lobe of the hypophysis should be abandoned. The author reasons that, since every cell of a sexually differentiated organism is either male or female, it is logical to consider the hypophysis of a male animal the source of a specifically male secretion. It is possible that these hormones of the male anterior hypophysis are chemically related to but not identical with those of the female organism. It may even be assumed that on the basis of a bisexual disposition of all gonochorists the male anterior hypophysis produces also a small quantity of female hormone, just as the female organism contains small amounts of the male sex hormone. Future experiments should show whether hormones from the anterior hypophysis of male animals will effect maturation of the testicles of infantile animals.

**Misinterpretation of Encephalogram**—Saamer investigated whether a forced position of the head during air inflation can cause a unilateral air distribution leading to a misinterpretation.

pretation of the encephalogram. She cites experiments proving that a forced position of the head, particularly a maximal leaning to the side, may lead to a greater accumulation of air on one side. However, this was not always the case but was observed in four out of eight postmortem encephalographies and in two out of six living children with cerebral disorders, in whom the encephalogram was made for diagnostic purposes. Unilateral accumulations of air seem to be particularly frequent in children from 3 to 18 months of age. The author thinks that this is probably due to the greater plasticity of the brain, to the open fontanel and to the larger subarachnoidal space. The excess pressure evidently favors the unilateral accumulation of air. The author concludes from these observations that during encephalography a vertical position of the head should be insisted on. If this position of the head cannot be maintained during air inflation, caution is necessary in interpreting an increased accumulation of air on one side of the brain.

**Acute Poliomyelitis of Brain Stem**—The case described by von Kiss and Hechst was one of the so-called pontine type of poliomyelitis. It was of interest because of the diagnostic difficulties it presented and because its histologic aspects illustrate the significance of system electivity. The disorder began with high fever, pains in the neck and diplopia. On the third day the child was brought to the clinic, and at this time there existed cerebellar ataxia, meningeal symptoms and ptosis with paresis of the ocular muscles. A meningeal process could be excluded on the basis of the examination of the cerebrospinal fluid. The author discusses the differentiation from influenza encephalitis and from epidemic encephalitis. The patient died and the postmortem diagnosis was based on the intensity of the histologic processes and on the diffusion of the changes in the nerve cells. The essential feature of the histologic picture was the destruction of cells in certain motor nuclei, which proved the so-called neurotropic system electivity.

**Hereditary Factor in Tuberculosis**—Studies on a material of 600 tuberculous patients revealed to Schubert that in 64 per cent a hereditary factor was involved. He thinks that in the other patients a massive tuberculous infection during childhood was responsible for the development of the tuberculosis. Children from tuberculous parents contract tuberculosis much easier than children from healthy parents. The author concludes that, from the eugenic point of view, propagation is inadvisable not only when either the man or the woman has tuberculosis but also when they descend from a tuberculous family.

**Plastic Repair of Congenital Luxation of Hip Joint**—Spitz states that the method which he first employed in 1921, was carried out in the following manner. After bloodless reposition of the head of the femur and after exposure of the acetabulum by Hoffa's incision, the upper or the posterior rim of the acetabulum is laid free. Then a slit 2 cm in depth is made with the aid of a fine chisel into the pelvic bone, obliquely from below upward. Into this slit is driven a bone splinter, 5 cm in length taken from the contralateral tibia. The joint is fixed by a well fitted plaster-of-paris cast left on for from three to four months. It was found that in the course of the years the bone splinter became thicker, so that finally it grasped like a hand and thus gave the head a firm hold. It is essential for the success of the treatment that the splinter be as wide as possible. If one splinter proves insufficient, a second one may be driven in at once or later. In the course of the

years the author employed the method in forty-five cases and simplified it so that now it can be done almost subcutaneously and can be employed even in small children. This he considers an especial advantage of his method.

**Removal of Breast or Radical Excision of Malignant Tumor**—Goldschmidt points out that some authorities recommend the complete removal of the breast and others irradiation only, some a radical operation combined with irradiation and others simple excision of the primary tumor from the breast and subsequent application of rays to the lymph vessels and glands. The latter method avoids the mutilation to which many women refuse to submit, and it takes account of the progress in irradiation therapy. The author employed this method in fifty-one cases. His observations indicate that the less differentiated forms of carcinoma are more suitable for this form of treatment than are the more highly differentiated forms. He does not consider completely solved the problem as to when complete removal is necessary and when a more conservative method may be employed and he admits that further studies will be necessary to decide where the line should be drawn between total removal of the breast and simple excision with subsequent irradiation. He reports a case in which total removal was urged but rejected and the subsequent development showed that total resection should have been done. He concludes that if proper use is made of the progress in ray therapy and if the histologic structure of the mammary carcinoma is given consideration it will not be necessary to resort to the mutilating radical operation in all cases. Observations that he made in the course of eight years with the less radical operation seem to indicate early excision of the primary tumor, and, if they are involved, removal of the axillary lymph nodes through a different incision, but during the same session, and subsequent irradiation if the histologic examination reveals a solid cancer of a lower stage of differentiation. If the cancer proves to be a highly differentiated one, radical removal would of course be preferable.

**Chorio-Epithelioma and Aschheim-Zondek Reaction**—Schwalm relates the history of a woman in whom, in the absence of clear clinical symptoms, the Aschheim-Zondek test of the urine aided in corroborating the suspicion of the presence of chorio epithelioma so that surgery was resorted to early enough. He emphasizes that the test is valuable not only in the diagnosis of chorio epithelioma but also in ascertaining the efficacy of the treatment and in the early detection of metastases.

**Connection Between Hypophysis and Genital Carcinoma**—Busse and Hoeverner point out that some authorities, particularly Hofbauer, assume a connection between hypophysis and genital carcinoma. In experiments on guinea pigs this author noted that after the administration of the hormone of the anterior lobe of the hypophysis certain changes developed in the vaginal portion of the uterus and he considered these changes precancerous proliferations of the epithelium. He also made observations on castrated guinea-pigs, into which anterior hypophyseal tissue had been implanted, and maintained that the same changes took place. In order to verify these results the authors duplicated his studies on forty sexually mature female guinea-pigs. The animals were castrated and then portions from the anterior hypophysis of hogs were implanted. A considerable number of animals served as controls. In summing up their observations the authors state that they never observed precancerous proliferations of the epithelium and that control animals showed the same changes as the animals which had been given implantations. Administration of the hormone of the anterior lobe of the hypophysis likewise caused no changes in the genitalia of castrated guinea pigs.

**Method of Influencing Trophic Processes**—Vishnevsky treated sixty-one patients presenting chronic, callous ulcers of the extremities by the method of procaine hydrochloride block of the nervous system. In fifty-one the ulcers healed promptly and remained healed during the following year. Twelve patients having spontaneous gangrene of the extremities were submitted to the same treatment. The results were strikingly good. Of these, six were permanently cured, six had a recurrence which, however, yielded to repeated injections. In two the process was not influenced and amputation became necessary. The method consisted of injecting from 50 to 60 cc of 0.25 per cent solution of procaine hydrochloride into the renal fascia (lumbar anesthesia) or of a circular block of the thigh the needle reaching down to the bone, utilizing from 200 to 250 cc of the solution of procaine hydrochloride. The author obtained the same effect when lumbar block was carried out on the side opposite that of the diseased extremity. It appeared that fractional stimulation of the nervous system by procaine hydrochloride was capable of changing the condition of the entire nervous system, as a result of which the local pathologic process was influenced. The recent concept of the gastroduodenal ulcer as a neurotrophic lesion suggested to the author the rationale of applying his method of nerve blocking to this disease as well. In forty-six cases presenting ulcerative disease of the stomach or duodenum, the results were good. The author likewise applied this method in the treatment of acute inflammatory processes. He was able to show in a number of cases that injection of an anesthetic fluid into an inflamed area is, contrary to the old notion entirely free from any danger. The most striking effect noted was the disappearance of the inflammatory edema. This was so constant as to suggest that edema is a neurotrophic disturbance. Excellent results were obtained in the treatment of carbuncles, erysipelas and various other acute and chronic inflammations.

**Pathogenesis of Rheumatic Disturbances**—Eyger reviews the existing theories with regard to the pathogenesis of rheumatic disease. On the basis of the work of Klinge and of Weintraud, as well as his own clinical experience, he accepts the concept of rheumatism as an allergic disease. According to this concept the organism is first sensitized by foreign proteins of bacterial or other origin, both exogenous and endogenous. Certain agencies, such as chilling or dampness, innocuous to a healthy organism, produce in the sensitized organism morbid processes of the most varied type and localization, such as eczema, bronchial asthma and rheumatism. The allergic process may for a time fail to localize itself and may cause a febrile state, the so-called rheumatic fever. At some later time the characteristic alterations in organs will manifest themselves. The rheumatic process attacks the mesenchymal tissue, the joints and the muscles, the heart and the blood vessels, the serous surfaces, the brain and the peripheral nerves, the skin and the larynx. The reason for particular localization in any given organ is not known. It may have something to do with overwork. The author proposes a classification that embraces the various rheumatic manifestations.

**Elimination of Urea and Renal Function**—Bjerring discusses the urea test of Addis and the creatinine test of Rehberg. The first determines the urea clearance and the second is based on the filtration resorption theory. The author found that within a fluctuation of from 10 to 150 of the creatinine concentration, and a fluctuation of from 13 to 90 mg per hundred cubic centimeters of the blood urea, there is a constant relation between the concentration index for urea and for creatinine. He reaches the conclusion that in the clinic the clearance test is superior to the filtration test not only because the determination of the urea belongs to the routine laboratory work but also because it is probably more reliable than the determination of creatinine, which necessitates a certain experience in the use of the colorimeter and a rather expensive equipment.

**Sugar Threshold and Renal Function**—Bjerring and Iversen relate the following observations: 1 The sugar resorption decreases only relatively according to the increasing sugar concentration in the blood. 2 There exists a linear correlation between the sugar content of the resorbed fluid and that of the blood. 3 With the same blood sugar content, the sugar solution absorbed by the kidney has a lower concentration in case of a decreasing blood sugar curve than in case of an increasing one. 4 Sugar content and total elimination of sugar in the urine are dependent on the blood sugar and on the concentration index. If the latter is kept constant, a parallelism may be produced between the sugar in the urine and the sugar content of the blood. 5 In acidosis the tubules are poisoned, with the result that the resorbed sugar solution becomes weak. 6 If the sugar content of the resorbed fluid remains for some time the same as the sugar content of the blood the sugar content of the urine will be found to be the same. 7 The elimination of increasing quantities of sugar is accompanied by a decreasing concentration index. 8 The same person eliminates under identical conditions the same quantity of sugar.

**Current Potential in Circulation and Pathogenesis of Hypertension**—Leiri shows that a current potential develops in the circulation and that it presents a resistance in the movement of the blood through the arteries. Changes that could produce an increased current potential have been observed in the blood and in the vascular wall of patients having hypertension, and it is possible that this plays a part in the pathogenesis of hypertension. This possibility is indicated by the favorable effect produced by carbon dioxide baths and by the inhalation of air with a negative electric charge.

**Relationship Between Plasma Proteins and Bone Marrow**—Determinations of the total protein and the more important fractions of protein in the plasma were made by Johansen in a series of patients who had diseases in the bone system. In primary tumors of the bone marrow, i.e. myelomas, greater variations were found in the plasma proteins than in cases of metastatic tumors of the bone system, although the distribution, the roentgenologic and other clinical features were nearly identical. The observations led the author to believe that there is a relationship between the maturity of the tumor cells in the bone marrow and the proportionate qualitative and quantitative changes of the plasma proteins.

- \*Anemia in Patients After Operation on Stomach J Dedichen —p 565
- \*Clinical and Roentgenologic Study on Results of Internal Treatment of Gastric and Duodenal Ulcers T Dale and H G Dedichen —p 585

**Internal Treatment of Gastric and Duodenal Ulcer**—Dedichen states that after examination with roentgenologic control in thirty-two patients with roentgenologically established gastric or duodenal ulcer, treated medically from 1926 to June 1931, showed satisfactory results in about 50 per cent, the results being slightly better for gastric than for duodenal ulcers. Recurrence was most frequent in men doing heavy physical work, often also under poor economic conditions. One of the most important factors in internal therapy is the management of the after-treatment. Internal treatment of ulcers deserves a larger place than it has held during the last twenty years, and the results of the treatment are and can be better than is generally acknowledged. The failure of internal treatment is most often due to too late diagnosis or to defective management of the treatment, particularly the after-treatment.

**Medical Treatment of Chronic Gastroduodenal Ulcers**—Jervell concludes from statistics on the end-results of medical treatment that good results can be counted on in from 40 to 50 per cent of the cases treated. He is inclined to consider early diagnosis and start of treatment the important feature in the treatment of ulcers and one too little emphasized, but he says that even after symptoms of more than twenty years' duration medical treatment may be effective, and niches apparently due to callous and penetrating ulcers not infrequently disappear under it. In after-treatment, economic conditions play a part. Statistics are presented to show that there is no great danger of perforation in the further course of chronic gastroduodenal ulcers, except in special cases in which there are painful ulcers on the anterior wall. The danger of hemorrhages after medical treatment is also slight. Mattisson's report in 1931 on after-examination in 1,491 cases of gastroduodenal ulcers showed that of 178 fatal cases twenty-three, or 141 per cent, were due to hemorrhage. Prophylactic operation could have been done only in ten, or 076 per cent, of the 1,491. Repeated grave hemorrhages are considered a weighty indication for surgical treatment. The author finds greater significance attached to erroneous diagnosis of callous ulcer when cancerous ulcer is present than to the actual development of cancer from the ulcer. The least suspicion of cancer or perforation indicates operation. Pyloric stenosis and hour-glass stomach afford strong indication for operation, but, as the part played by the spastic factor is uncertain, medical treatment is worth trying. In acute hemorrhage from ulcers, internal treatment seems safer than operative treatment, but, in the more oozing chronic bleeding, surgical intervention must not be too long delayed. Before operation for gastroduodenal ulcers medical treatment should be tried. He regards two carefully performed courses of treatment with necessary after-treatment as the minimum requirement.

**Indications for Treatment of Gastric Ulcers**—Holst asserts that internal treatment and surgical treatment of ulcers do not compete but supplement each other. Surgical indications are present only in cases of definite complications. Except in cases of perforation he never operates for gastric or duodenal ulcer unless the ulcer is roentgenologically confirmed. Of 305 cases of gastric and duodenal ulcer in which operation was performed between 1919 and 1933, gastro-enterostomy was done in 136, and resection in 169. Mild cases of gastric anemia, readily influenced by iron medication were frequently observed after resection. The decisive factor in the choice between gastro-enterostomy and resection must be the end-results. Late complications are more frequent and more grave after gastro-enterostomy than after resection, and the study of the pathology of the operated stomach' in cases from various Norwegian

hospitals shows resection, with extirpation of the ulcer, to be superior to gastro-enterostomy.

**Operative Treatment of Gastric and Duodenal Ulcers**—Nicolaysen says that the association of gastritis with peptic ulcers is less frequent in Norway than in central Europe, but more frequent than in the United States. He considers gastro-enterostomy indicated in pyloric stenosis with large retention and dilatation of the stomach, irrespective of age. As a general rule, gastro-enterostomy should be the method after 45, in women and in cases of gastric ulcer the age for gastro-enterostomy can apparently be put slightly lower without special danger of jejunal ulcer. In resection he uses the anterior no loop as easier than posterior anastomosis and always removes more than one third of the stomach. Transient stomach retention in the first days after operation is frequent. The achylic anemia following operation yields to iron medication. He recommends operation in repeated, more massive hemorrhages and in a single massive hemorrhage due to chronic ulcer, in which, as also in all cases of suspected cancer, he prefers resection to gastro-enterostomy irrespective of age. In operative treatment indicated because of chronic symptoms, resistance to dietetic treatment, and for economic or geographic reasons, he prefers resection in all patients under 40, especially in men, in duodenal ulcers, and in high acid values and gastritis. With gastro-enterostomy mainly for older persons and resection for the younger, he considers resection a relatively safe operation, when well done, and offering far greater certainty of good results. In technically difficult cases, gastro-enterostomy is advised. In all diagnosed cases of ulcer, one regular course of dietetic treatment should first be given. In every case of gastric ulcer which after this treatment shows a roentgenologic niche, operation should be done, and in every case of duodenal ulcer, even with niche, continued diet may be advised if the patient can with a relatively liberal diet remain free from symptoms. He emphasizes the need for individualized treatment in each case of gastroduodenal ulcer.

**Necropsy in Fatal Hemorrhage from Gastric and Duodenal Ulcers**—Out of 4,460 necropsies, Hjort found gastric and duodenal ulcers in 108 cases (245 per cent), with fatal hemorrhage in twenty-two (20 per cent) of these (nineteen from gastric, three from duodenal ulcers). According to the local results of necropsy, fourteen cases seemed to be in an operable condition, five in an inoperable condition and three doubtful on the basis of the general results, about one half seemed in an operable condition. Attention is called to the operative difficulty in case of erosion of the splenic artery. Thirteen cases of gastric and duodenal hemorrhages not due to round ulcer are also reported. While the material supports the view that selected patients having acute grave hemorrhages from gastric and duodenal ulcers may be successfully operated on, the author emphasizes that the general results in half of the cases revealed pronounced vascular and organic disorders.

**Anemia in Patients After Operation on Stomach**—Dedichen's investigations show anemia, usually of secondary type, sometimes of pernicious type after resection of the stomach mainly according to Polya. The tendency to anemia in achylia following operation is greater than in spontaneous achylia and anemia may appear without postoperative achylia. The anemia cannot therefore depend only on the achylia. Possibly the excision of so large a part of the stomach is a factor, and perhaps also the rapid emptying of the stomach with consequent abnormal loading of the upper intestine. It seems at all events justifiable in choice of operative method, especially in younger women to bear the postoperative anemia in mind.

**Results of Internal Treatment of Gastric and Duodenal Ulcer**—Dale and Dedichen describe the clinical and roentgenologic results before and after treatment in twenty-eight cases. The ulcer niche usually disappeared after from four to six weeks, but some cases with a large niche required from two to four weeks more. Recovery was seen in old patients with large ulcers. After-examination in forty-five patients from two and a half to eleven years after treatment showed recovery in about one half of the cases, including cases with history of ulcers for from ten to thirty-two years and roentgenologically large niches.

## THE MORTALITY FROM HEART DISEASE A CHALLENGE

CHAIRMAN'S ADDRESS

CHARLES T. STONE, M.D.  
GALVESTON, TEXAS

In the United States today, heart disease in its various forms holds first place in the list of causes of death. Naturally, any condition that is of such far-reaching importance in the lives of our people is of unusual interest to physicians generally, but it is also of particular interest to them personally because carefully collected figures show conclusively that the death rate from heart disease is definitely higher among the members of the medical profession than it is among the general population. This fact is probably of considerable significance in the whole problem of the mortality from heart disease, since it provides a clear-cut opportunity for the evaluation of some of the etiologic factors involved. The life of the physician is more or less standardized by the nature of his profession with its constant nervous tension, irregular hours, heavy responsibilities and hard work. If these forces, projected into the lives of a large number of individuals, develop a class that is more susceptible to heart disease than are other social groups, it is practically certain that at least a partial insight into the larger aspects of the problem can be obtained. How well this apparently justified and obvious conclusion fits in with the established facts may later be observed.

### THE INCREASE OF HEART DISEASE

If one consults the mortality statistics of the United States Census Bureau, two outstanding facts are at once apparent. The first is that heart disease is responsible for about two and one-fourth times as many deaths as its nearest rival, cancer, the second is that heart disease is steadily increasing in frequency. As computed from this source, the death rate from heart disease in 1900 was 132 per hundred thousand of population, while in 1932 it was 224 per hundred thousand—an increase of approximately 70 per cent. There are those who believe that the alleged increase of heart disease is more apparent than real. They attempt to explain the higher rates in recent years on the basis of changes in the use of terminology and the designation as heart disease of various correlated conditions in the blood vessels and kidneys. That these factors may have some bearing on the greater frequency with which heart disease finds its way on death certificates can hardly be denied, but that they account for an

increase of 70 per cent in thirty-two years seems quite exaggerated. During the past fifteen or twenty years the popular appreciation by physicians of the clinical features of coronary thrombosis has undoubtedly added to the total number of heart disease diagnoses appearing in mortality statistics. However, if the percentage of this type of heart disease is estimated in a large group of cardiac cases it is found to be relatively small, so that coronary artery disease as a comparatively recent clinical entity can account for but a small part of the increasing frequency of heart disease as a whole. If one studies the carefully compiled mortality rates for the large cities and the life insurance companies, in which perhaps the most reliable figures are to be found, one sees that the trend in every instance is the same—a decidedly increasing death rate from heart disease. Then the opinion of capable clinicians who have practiced through the years from 1900 to the present is emphatically that heart disease is more commonly encountered now than it was thirty years ago.

An important fact brought out by the age incidence statistics is that heart disease has shown marked increase in frequency only in individuals past the thirtieth year of life. Before 30, fewer people die from infectious diseases now than was the case in 1900, this is in effect saying that, by avoiding serious infections, more have been carried into the age groups where heart disease takes its greatest toll. Whatever the actual facts may be as regards the increase of heart disease, however, it is sufficient for the moment to realize that it destroys more than twice as many lives as does its nearest competitor. Therefore from a public health point of view it is no exaggeration to state that the most outstanding challenge to modern medicine is the mortality from heart disease.

Almost fifty years ago, Osler said "It is of use from time to time to take stock, so to speak, of our knowledge of a particular disease, to see exactly where we stand in regard to it, to inquire to what conclusions the accumulated facts seem to point, and to ascertain in what direction we may look for fruitful investigations in the future." It is with this attitude of mind that the present discussion is undertaken. Many facts that afford definite clues are at hand, it should be our purpose to use that material which is available to add to the existing knowledge of the subject, to sponsor research that will clarify certain etiologic factors in heart disease, and to strive for the development of conditions that may be antagonistic to the operation of these factors.

### THE CAUSES OF HEART DISEASE

Within the last fifteen years the relative importance of the various causes of heart disease has become increasingly appreciated and more generally understood. This is due largely to the adoption of the prac-

tice of classifying heart ailments from the standpoint of etiology as well as of alterations in structure and function. In 1920 this composite type of study was instituted almost simultaneously in a few of the larger Eastern clinics, where its value was at once apparent. Soon thereafter, under the sponsorship of the American Heart Association, a uniform system for the classification of heart disease from all angles resulted in its widespread use in teaching hospitals, and more recently the same organization has fostered the development of heart clinics in ever increasing numbers throughout the country. The effect of these efforts has been to revolutionize, more or less, the concepts of heart disease in the minds of physicians, so that today no cardiac diagnosis can be considered complete that does not include the three cardinal features of etiology, tissue change and functional effect. Not only has a more adequate knowledge of the clinical manifestations and interrelationships of the manifold factors in heart disease been established—that is to say, more accurate diagnosis, more exact prognosis and more rational therapy—but important facts that may materially advance the cause of the unified movement for the prevention of heart disease have been accumulated. In fact, the knowledge has progressed to a point at which it is now possible to project offensives along a wide front in battle with the forces that ultimately destroy more lives than the combined powers of the next two most important causes of death.

During the last decade there have been reported in the literature from every geographic section of the United States numerous studies of the incidence of the different types of heart disease. Quite naturally there are variations in the frequency of individual types in different localities, the explanation for which is traceable to climatic, racial, social and other influences. However, it is now positively known that four conditions—rheumatic fever, hypertension, arteriosclerosis and syphilis—are responsible for approximately 90 per cent of all heart disease. The remaining 10 per cent is accounted for by congenital defects, infectious processes (acute and subacute bacterial endocarditis and pericarditis), thyrotoxicosis, chemical toxins, chronic pulmonary diseases with resulting increase in the tension in the lesser circulation, traumas, tumors, and a small percentage of unknown factors. It is thus at once apparent that the main problem lies in the conquest of the four major factors that produce heart disease.

If the figures from statistical surveys are studied, either rheumatic fever or hypertension will be first in the list. Rheumatic fever predominates in the North and East, but elsewhere hypertension is the most important cause. Generally speaking, heart disease is approximately twice as frequent in the Northeastern section of the United States as it is in the far South, while the Middle West and Central tier of states stands in an intermediate position. An analysis of the type incidence of heart disease in these various areas establishes the irrefutable fact that the difference is due chiefly to the high incidence of rheumatic fever in those areas in which the death rate is the highest, and its very low incidence in the South, in other words, it is the result of a climatic difference in the two sections. In certain areas, particularly in the South, where the Negro population is greatest, syphilis is more often a cause of heart disease than it is in other geographic locations. Goitrous districts naturally furnish a large number of cases of thyrotoxic heart dis-

ease, but even with these and other variants taken into consideration the four chief causes remain the same. In the order of frequency with which they are operative throughout the country as a whole, hypertension, rheumatic fever, arteriosclerosis and syphilis seems to be the proper sequence of "the Four Horsemen" in the causation of nine out of ten cases of heart disease. This fact narrows the field for further study, and it should indicate the necessity of concentrating the attack on the important salients along the battlefield. A brief consideration of the problems presented by these factors will serve to emphasize the need for investigation of leads that appear to hold the greatest promise.

#### HYPERTENSIVE HEART DISEASE

Vascular hypertension is increasing, if the statistical data and physicians' opinions are not misleading. This is in accord with well established fact, which indicates that the cause of hypertension is to a considerable extent a result of the nervous factors incident to and consequent on the complexities of modern life. For instance, native Chinese seldom have hypertension, but those who have been transplanted into the life of the Occident show it to a very considerable degree. Similarly, among African natives hypertension is practically nonexistent, while in this country their direct descendants have a higher incidence of abnormally high blood pressure than do the whites living in the same districts. In Japan the urban population has a high hypertension rate, which is in striking contrast to the rarity of the condition among the rural inhabitants. According to a dependable informant, a close analogy is to be found in the high and low classes of the general population of Mexico, whereas in our own Southern cities, to which the erstwhile Mexican peon has migrated in large numbers, many are found to have hypertension and its sequelae. These plain facts require no elaboration. They lead straight through to the conclusion that hypertension is to a large extent a total personality reaction to that which we have elected to call "modern civilization."

The mechanism by which the anxiety, high nervous tension, and the ever pressing struggle for survival—all important factors in the daily average American life—operate to produce hypertension is partly understood. In the continued increase in arteriolar tonus resulting from excessive vasoconstriction is to be found the underlying mechanical impediment to the blood flow which provokes a blood pressure increase, and this in time becomes permanent, ultimately resulting in a generalized arteriolar sclerosis, with all the disastrous complications incident thereto. What produces the vasoconstriction is wholly unknown. It may be that psychic impulses through direct pathway communications act as stimuli to the sympathetic nervous system, the preponderant effect of which is a general heightening of arteriolar tone. Or emotional responses may provoke a hypersecretion of vasopressor substances of endocrine origin—e. g., from the suprarenals, pituitary and thyroid—which supply the vasoconstrictor stimulus. These are the most plausible concepts of the question at the moment, but subsequent research might conceivably produce different views and furnish newer methods of approach. Obesity, hereditary influences, chronic intoxications, severe exertion and other important factors need to be studied with regard to their relationship to the larger problem of hypertension, and their effects should then be correlated with those derived from other sources. However, the real crux

of the situation lies in ascertaining all of the etiologic factors in the production of essential hypertension in otherwise normal individuals. When that has been accomplished, medicine will be in a commanding position to attempt prophylactic measures with some expectation of success. Then may there be witnessed a reversal of the now rising incidence of hypertension and one of its greatest tragedies, hypertensive heart disease, in all its clinical forms.

#### RHEUMATIC FEVER

Rheumatic fever is apparently both a climatologic and a bacteriologic problem. Unfortunately it occurs with greatest frequency in the most densely populated part of the country, which fact together with the extremely high incidence of accompanying cardiac complications, makes it a disease of paramount significance in the larger aspects of the mortality from heart disease. The difficulty is further enhanced by reason of the fact that the true cause and nature of rheumatic fever are not known. The mass of the evidence suggests strongly that it is a systemic infection with a peculiar predisposition to cardiac involvement. If speculation, based on the success already achieved in other infectious diseases, may be permitted, one is justified in the belief that rheumatic fever, like typhoid, diphtheria and tuberculosis, may soon be classified among the diseases with a definitely known cause and a diminishing incidence ratio. When and if its etiology is settled, then may one expect methods of prevention and treatment to be developed that may go far toward diminishing the second most important type of heart disease, an achievement that would carry especial significance, because rheumatic heart disease exacts its severest penalties from the ranks of children, adolescents and young adults.

#### ARTERIOSCLEROTIC HEART DISEASE

The statement to the effect that every one will die from arteriosclerosis if he lives long enough is probably true, and by the same token many deaths in the later decades of life are caused by arteriosclerotic heart disease. It is intended to include in this category only those cases in which the heart disease results from the arteriosclerosis of senescence—i.e., the degenerative type—and to exclude those in which an existing arteriosclerosis is secondary to vascular hypertension. The latter type more properly belongs to hypertensive heart disease, although at times there is an overlapping of the two types, and the distinction between them is not always sharply demarcated. Inspection of a graphic chart of deaths from heart disease by age groups shows an almost vertical rise in the curve for the age period from 55 to 70 years. That is, of course the degenerative period when arteriosclerosis of some degree is present in most people, and most of the cardiac deaths in this group are due to arteriosclerotic heart disease, particularly is this true in the decade from 60 to 70. From 50 to 60 years of age, hypertensive heart disease still holds the premier position.

To one who is biologically minded there appears little to support the belief that the human animal was constructed to live far beyond the seventh decade. By reducing the mortality from infectious diseases in younger life, the present average age of our people has been prolonged to 59 years—a signal accomplishment—but further additions to the average expectancy will come gradually and will swell the ranks of the arteriosclerotic. This will occur in the event of real

progress in the control of hypertension and rheumatic fever, in which case arteriosclerotic heart disease will in time become the foremost type of heart disease, one for which there appears to be no biologic antidote. Moreover, if prior to the age of 60 there is a decrease in deaths from all causes, there will be a proportional increase in the number of deaths from arteriosclerosis and consequently from arteriosclerotic heart disease. Arteriosclerosis, as we know it, is bound by the laws that govern the average age of a species. It is ultimately inevitable, therefore, and not subject to change.

#### SYPHILITIC HEART DISEASE

Syphilis continues to rank among the major causes of heart disease despite the fact that as such it is perfectly preventable, and syphilitic heart disease should therefore not exist at all. Adequate treatment of all early syphilis would automatically erase this type of heart disease from further consideration. Whenever the attitude, both lay and professional, toward syphilis changes so that it ceases to be considered a "misconduct disease," and when we begin earnestly and seriously to conduct educational campaigns against it, a single case of syphilitic heart disease will be like one of typhoid today, almost a medical oddity. So long as individuals hide their syphilis because of the fear of public condemnation, and so long as they continue to receive insufficient treatment for the cure of early syphilis, there will be all too numerous cases of the most easily preventable of all heart disease, syphilitic aortitis and aortic insufficiency.

Some improvement with regard to the minor causes of cardiac abnormalities, excepting congenital heart disease and the rare cases of tumors of the heart, might reasonably be anticipated because of the fact that thyrotoxic states account for so large a number of cases in this group. Because of a better understanding of the underlying principles connected with its pathogenesis, much has been accomplished in the prevention of goiter. Furthermore, the clinical application of basal metabolic rate determination has greatly simplified the matter of diagnosis, and the introduction of iodine into the preoperative therapy of thyrotoxicosis has rendered the prognosis more favorable now than ever before.

#### SUMMARY AND CONCLUSION

Regardless of how one feels about the alleged increase in the number of deaths assigned to cardiac causes, there can be no real difference of opinion as to the importance of heart disease as the foremost cause of death. To know that four primary causes are responsible for the great majority of cases of heart disease assists in focusing attention on the strategic points and suggests the lines along which investigation should be initiated and pursued. In short, if good results are to be obtained, rational methods for the prevention and treatment of essential hypertension and rheumatic fever, based on a complete understanding of their etiology, must be developed. Syphilitic heart disease can be eradicated by the means now available. In the prevention of arteriosclerotic heart disease there is little to hope for.

The whole problem of the prevention of heart disease is a formidable one. Investigation must be pursued critically and in accordance with the advice John Hunter gave Jenner relative to the latter's studies on vaccination against smallpox. "Do not think, but try, be patient, be accurate." It is ours to plan and conduct the campaign in the light of facts that are known and

with those that will be accumulated in the future. In the conquest of the causes of heart disease an enormous responsibility is placed on the medical profession, one that by reason of its magnitude should serve to stimulate our best efforts. The benefits that will accrue to mankind, in the event of successful achievement, will constitute medicine's outstanding victory over the most ominous leader of all time among "the Men of Death."

## THE INTRACUTANEOUS QUANTITATIVE TUBERCULIN TEST

IN THE DIAGNOSIS OF ACTIVE TUBERCULOSIS

DAVID AYMAN, M.D.

BOSTON

The diagnosis of active tuberculosis is aided but little by the positive skin tuberculin test (Pirquet or Mantoux tests), for more than 90 per cent of healthy adults will react positively to this test. On the other hand, the diagnosis of active tuberculosis can be made in more than 90 per cent of people who have positive skin reactions after the intracutaneous injection of properly diluted tuberculin, according to recent reports. The present study has attempted to determine further the value of such a test with diluted tuberculin.

### RATIONALE OF SUCH A TEST

The use of the dilute tuberculin reaction is based on the following simplified interpretation of experimental and clinical evidence. Past or present infection with tuberculosis makes the individual sensitive to tuberculin. One way of demonstrating this sensitivity is by a positive skin reaction following the usual skin injection of Koch's old tuberculin (Pirquet scratch method or Mantoux intracutaneous method). This sensitivity varies more or less directly with the activity of the disease.<sup>1</sup> Therefore a person with active tuberculosis should react to a greater dilution of tuberculin than a person with old healed tuberculosis. In other words, the tuberculin test may be used as a quantitative test. For a summary of the evidence on which this explanation is based, one should refer to the paper of Atsatt.<sup>2</sup>

### LITERATURE

The literature concerning the use of the skin tuberculin test in a quantitative manner may be divided into the studies using the relatively inaccurate Pirquet scratch method and those using the intracutaneous Mantoux method.

The studies using different dilutions of tuberculin by the Pirquet scratch method have shown that even by quantitating the Pirquet test one may separate active from latent tuberculous infections. For the details of these studies, one should refer to the paper by King.<sup>3</sup> However, in order to use the tuberculin skin test as a quantitative test, it is best not to use the Pirquet scratch method, for the actual amount of tuberculin absorbed by the skin through the scratch is not known.

Of more importance to the present investigation are the studies using the intracutaneous injection of a

known amount of tuberculin (Mantoux method). There have been three such studies in recent years, the results of which are enhanced by the fact that they all used a similar method and technic. In these investigations the authors experimented with different dilutions of tuberculin until they found a dilution 0.1 cc of which gave positive reactions in their cases of active tuberculosis and negative reactions in their controls with no active tuberculosis. The dilution that was finally used varied in each study, for, since the standardization of old tuberculin is unsatisfactory, the various lots of old tuberculin used by the different investigators varied markedly in strength. Thus, the final dilution used by the different observers was 1:10,000 in one study, 1:20,000 in the second, and 1:100,000 in the third. Whereas Atsatt<sup>2</sup> and Blair and Galland<sup>4</sup> used control injections of saline solution, King<sup>3</sup> did not use control injections.

The results of the studies with these dilutions were strikingly successful. Thus, Atsatt found 92 per cent of eighty-five tuberculous patients reacting positively, while 90 per cent of 126 control ward patients reacted negatively. Blair and Galland found 90 per cent of 121 tuberculous patients reacting positively, while 92 per cent of 350 control ward cases reacted negatively. King did not separate his control cases from his tuberculous cases but did find that, of 225 patients comprising both tuberculous and control cases, there was a 91 per cent agreement with clinical observations. There were about 80 cases of active tuberculosis in his group.<sup>5</sup>

When these investigations are discussed individually it is to be noted that Atsatt, the author of the original of these studies in 1927, did not mention what he interpreted as a positive reaction. It is probably to be inferred, therefore, that Atsatt considered a positive reaction to be a reaction of any size to his dilution of 1:10,000. Blair and Galland stated that their criterion of a positive reaction was the formation of an indurated cutaneous nodule, whatever its size, usually accompanied by erythema. King considered a positive reaction to be an area of erythema, nearly always indurated, 1 cm or more in diameter.

The age and type of tuberculous patients used in these observations varied. Atsatt, and Blair and Galland carried out their studies exclusively in cases of bone and joint tuberculosis, both in children and in adults. King made his observations chiefly in adults with active pulmonary tuberculosis, only a few of whom were seriously ill at the time of the test.<sup>5</sup> Except for a few cases, it was inferred in the reports of Atsatt and of Blair and Galland that their patients were in good condition although their tuberculosis was active.

### METHOD OF PRESENT STUDY

First, different dilutions of a given tuberculin were intracutaneously injected in a group of clinically non-tuberculous ward patients, and the size of the positive skin reactions were noted. Old tuberculin prepared by the Massachusetts State Laboratory was secured in sufficient quantity so that the same batch lasted throughout the entire study. This tuberculin was then carefully made up each week in dilutions of 1:1,000, 1:10,000, 1:25,000, 1:50,000, 1:100,000, 1:500,000, 1:1,000,000 and 1:10,000,000. Sterile Ringer's solution was the diluent, to which 0.2 per cent phenol was

added as a preservative. One cc tuberculin syringes and 27 gage needles were used. For a short time, 0.5 cc syringes made by a different company were also used, but it was found that 0.1 cc injected from such a syringe invariably produced a smaller wheal than 0.1 cc injected from the 1 cc syringe. Therefore, only 1 cc syringes made by one company were used. Leakage around the hub of the syringe occasionally occurred in older syringes, so that such injections were repeated. One-tenth cubic centimeter of each of the aforementioned dilutions was injected at the same time into the forearms of a group of ward patients. In most cases, the saline-phenol control was also injected. In one group of patients, the use of a glycerin broth control containing the same amount of broth as that present in the diluted tuberculin was also tried. The reactions were always read at the end of forty-eight hours, but in many cases also at the end of twenty-four and seventy-two hours. The size of the reactions was measured in millimeters in three dimensions—width, breadth and height—the measurement of the height being obviously done roughly. In most positive reactions an area of induration was present, and this area was measured rather than the larger area of erythema that was usually present. When erythema only was present, and the control had no erythema, the area of redness was measured, the height being recorded as zero. The subjects utilized were unselected patients admitted to the medical wards of the Peter Bent Brigham Hospital with the usual variety of diagnoses that are encountered in a general medical ward. Eighty-five per cent of the patients were 30 years or more of age.

The next step was to determine the reaction of patients with active tuberculosis to these dilutions of tuberculin. To avoid possible excessive reactions, the

tions of all the dilutions. First, considering the percentage of positive reactions regardless of their size, it is seen that 89 per cent of the patients reacted to 0.1 cc of the 1:1,000 dilution, while increasing dilutions gave a decreasing incidence of reactions. In this group are placed reactions of even 1 by 1 mm in size, provided the saline control showed no reaction. It is seen that 20 per cent reacted to the 1:1,000,000 dilution, although only sixty-five were tested with this dilution.

As to the incidence of positive reactions when only reactions 5 by 5 mm or more were counted, the 1:1,000 dilution gave 87 per cent positive reactions,

TABLE 2—Incidence and Size of Reactions to the 1:100,000 Dilution of Old Tuberculin in Patients Who Had Roentgen Studies of Chest

Number of Patients and X-Ray Examinations	Number of Patients with Reactions 10 by 9 mm or More	Number of Patients with Reactions 8 by 7 mm or more (Including 10 by 9 mm or More)
106 negative X-rays	2	6
13 healed tuberculosis	3	5
4 minimal tuberculosis	0	0
7 active tuberculosis clinically and by X-rays	3	4

the 1:100,000 dilution gave 15 per cent reactions, the 1:500,000 only 4 per cent reactions, and the 1:1,000,000 only 5 per cent reactions.

If 8 by 7 mm is considered the lower limit in size of a positive reaction, the 1:1,000 dilution gave 85 per cent positive reactions, the 1:50,000 gave 12 per cent positives, the 1:100,000 gave 6 per cent positives, the 1:500,000 gave 4 per cent positives, and the 1:1,000,000 gave 3 per cent positive reactions.

Finally, when only reactions of 10 by 9 mm or more are considered as positive, the 1:1,000 dilution gave 80 per cent positive reactions, the 1:50,000 gave 3 per cent, the 1:100,000 gave 2.6 per cent, the 1:500,000 gave 1.5 per cent, and the 1:1,000,000 gave 3 per cent. Both patients who reacted to the 1:500,000 and the 1:1,000,000 dilution with areas 10 by 9 mm or more also reacted to the glycerin broth control.

**2 Analysis of Reactions in Patients in Whom Roentgenograms of the Chest Were Taken.**—One hundred and twenty-three patients of this clinically nontuberculous group had roentgenograms of the chest taken as part of the routine study in the wards. Of these 123 patients, the roentgenograms were reported as negative in 106, in thirteen the report was old healed tuberculosis, and in four the report was minimal tuberculosis. Of the latter three cases, none presented fever or positive sputums. Table 2 shows the incidence and size of reactions to the 1:100,000 dilution in these 123 cases. Thus, of 106 patients with negative chest plates, two, or 1.9 per cent, reacted with areas 10 by 9 mm or more in size, while six reacted with areas 8 by 7 mm or more in size. Of thirteen patients with the roentgen report of healed tuberculosis, three, or 23 per cent, reacted with areas 10 by 9 or more. Of four patients with roentgen reports of minimal tuberculosis but with no fever or positive sputums, none reacted. In contrast of seven patients with active tuberculosis seen in the ward, three, or 43 per cent, reacted with areas 10 by 9 mm or more and four reacted with areas 8 by 7 mm or more. The three patients who did not react were moribund.

**3 Reactions of Patients with Active Pulmonary Tuberculosis.**—Table 3 presents the incidence and size

dilutions were not all given at once but rather the weakest dilutions were first administered. The patients utilized for this part of the investigation were adult unselected patients with pulmonary tuberculosis in the wards of the Boston Sanatorium. Many of these patients were seriously ill, and some were moribund. Ninety per cent of these patients had positive sputums.

#### RESULTS

**1 Reactions of Nontuberculous Patients to Different Dilutions of Tuberculin.**—Table 1 shows the different sizes and incidence of positive reactions to the injection of varying dilutions of old tuberculin into clinically nontuberculous patients. There were 223 such patients who were studied, not all of whom were given injec-

of reactions to varying dilutions of old tuberculin injected intracutaneously into patients with active pulmonary tuberculosis. It is seen that 98 per cent react positively to the dilution 1 10,000, all with reactions 10 by 9 mm or more in size. However, in the other dilutions, the incidence of reactions 10 by 9 mm or more is much less. Thus, in the 1 25,000 dilution the incidence of positives is 73 per cent, in the 1 50,000, 69 per cent react with 10 by 9 mm or more, in the dilution 1 100,000, only 47 per cent react with an area 10 by 9 mm or more. However, the latter is in contrast to 26 per cent of positive reactions 10 by 9 mm or more, in the dilution of 1 100,000 in nontuberculous patients. These high percentages of reactions by unselected tuberculous patients to weak dilutions of tuberculin are in marked contrast to the low incidence of reactions to weak dilutions in the nontuberculous.

Since only 47 per cent of the patients with active tuberculosis reacted to the 1 100,000 dilution with areas 10 by 9 mm or more in size, it is important to determine, if possible, why the remaining 53 per cent did not react similarly. The important factor appears to be the general state of the patient, as manifested by the degree of toxemia, height of fever and the like. It is of value to note whether there is any correlation in the tuberculous patients between the height of the fever and the degree of reaction to tuberculin.

**4 Height of Fever Versus Degree of Tuberculin Reaction in Tuberculous Patients**—Table 4 presents the incidence of fever in the patients who reacted to the 1 100,000 dilution with an area 10 by 9 mm or more in size, as compared with the incidence of fever in those who reacted with lesser sized reactions to this dilution. Not only the incidence of fever per se but the incidence of different heights of fever was determined in the tuberculous patients in relation to the size of their reactions to the 1 100,000 dilution. It is

dilutions, sixteen, or 84 per cent, had fever, more than 60 per cent of whom had fever of 102 or more.

It is clear from table 4 that, the smaller the size of reaction to the 1 100,000 dilution of tuberculin in patients with active tuberculosis, the more likely is it that such patients have considerable fever and are quite toxic. The same holds true for the other dilutions and the size of the reactions to them.

One other factor, which was usually present in the patients with high fever and toxemia but which also occurred without fever, was the exudative bronchopneumonic type of reaction, as seen by the roentgen

TABLE 4—Incidence and Height of Fever Versus Size of Reactions to 1 100,000 Dilution of Old Tuberculin, in Patients with Active Tuberculosis

Number of Patients	Size of Reaction to 1 100,000	Number and per Cent of Patients				
		With Fever at Time of Test	With 99.5 or Less	With 99.5 to 100.5	With 101 up to 102 Inclusive	With 102 or More
70	20 by 0 mm or more	21 (30%)	18* (85%)	2 (9.5%)	1 (4.7%)	0
34	5 by 5 mm to but not including 10 by 0 mm	27 (80%)	14 (51%)	9 (33%)	2 (7%)	2 (7%)
10	1 by 1 mm to but not including 5 by 5 mm	9 (90%)	5 (55%)	2 (22%)	1 (11%)	1 (11%)
19	No reaction	16 (84%)	2 (12%)	1 (6%)	3 (18%)	10 (60%)

\* Only occasional fever.

examination. This bronchopneumonic reaction was often associated with little or no reaction to the lower dilutions of tuberculin.

Analysis, therefore, of the tuberculous patients who did not react to the weak dilutions of tuberculin with areas 10 by 9 mm or more showed that practically all of them had either high fever or marked bronchopneumonic areas, or both. All these poor reactors were almost invariably advanced or moribund cases. If the poorly reacting patients with high fever and bronchopneumonic areas are subtracted from all the tuberculous patients, it is found that the dilute tuberculin test has a 93 per cent agreement with the clinical observations when the 1 50,000 dilution is used, and 83 per cent agreement when the 1 100,000 dilution is used.

COMMENT

It seems clear that with a given batch of old tuberculin it is easily possible to determine a dilution of this which will give a minimum of positive reactions of a certain size in patients without active tuberculosis and a maximum of such positive reactions in patients with active tuberculosis. More specifically, in the present study a 1 50,000 dilution of old tuberculin injected into 202 nontuberculous patients was found to give 97 per cent negative results, i. e., reactions less than 10 by 9 mm in size. The same dilution injected into eighty-two patients with active tuberculosis gave 69 per cent of positive reactions 10 by 9 mm or more in size, and when severely ill patients with high fever and bronchopneumonic areas in the lungs were subtracted from the total tuberculous group, 93 per cent of the tuberculous patients gave adequate positive reactions 10 by 9 mm or more in size. In seriously ill patients it is known that the allergic responses are diminished or absent, and since all these patients had every symptom and sign of active tuberculosis, their diagnosis is obvious without the dilute tuberculin test. It therefore seems valid to subtract these seriously ill patients from

TABLE 3—Reactions of Patients with Active Tuberculosis to Different Dilutions of Old Tuberculin

	Dilution of Tuberculin					Size of Reactions
	1 10,000	1 25,000	1 50,000	1 100,000	1 100,000

Per cent of positive reactions	98	73	69	47	12	

seen that, of seventy patients with areas 10 by 9 mm or more to the dilution 1 100,000, only 30 per cent had fever, 85 per cent of these patients with fever had occasionally a fever of 99.5 or less, and none had 102 or more. Of thirty-four patients who reacted to the 1 100,000 dilution with areas 5 by 5 up to but not including 10 by 9 mm, twenty-seven, or 80 per cent, had fever, of these twenty-seven patients, fourteen, or 51 per cent, had a fever of 99.5 or less, and two had a fever 102 or more. Of ten patients with reactions 1 by 1 up to but not including 5 by 5 mm, nine, or 90 per cent, had fever, only five, or 55 per cent, of these had fever of 99.5 or less, while one, or 11 per cent, had fever of 102 or more. Finally, of the nineteen tuberculous patients not reacting at all to the 1 100,000

the total group. Also, the fact that such dilute reactions occur chiefly when the patient is only mildly or moderately ill rather than moribund would appear to enhance the value of the test, for the difficulty in the diagnosis of tuberculosis is greatest in those patients who are not yet seriously ill.

With only 3 per cent of clinically nontuberculous patients reacting to the 1:50,000 dilution with areas 10 by 9 mm or more, and from 69 to 93 per cent of such positive reactions in patients with active tuberculosis (depending on whether one includes seriously ill and moribund patients), I believe that such a test has definite diagnostic value. This is in complete agreement with the previous studies. Since it is a specific test, unlike the nonspecific white blood cell count or fever and pulse chart, it would seem to merit as much use as these methods in the diagnosis of active tuberculosis. It is very unlikely that such weak dilutions will produce other than skin reactions. I have not encountered a single focal or general reaction after the 1:50,000 dilution.

With the recent availability of the crystalline tuberculo-protein, it should soon be simple to determine once for all a dilution of this tuberculo-protein which will give these reactions. Then such a dilution will always be the one to use, whereas at present the proper dilution of the old tuberculin will have to be determined for each batch.

371 Commonwealth Avenue

## HEART DISEASE AMONG ADOLESCENT SCHOOL CHILDREN OF NEW YORK CITY

MORRIS GOODMAN, M.D.

AND

JOSEPHINE W. PRESCOTT, M.A.  
NEW YORK

In a recent communication we reported the organization, procedure and method of examination of the Diagnostic Cardiac Clinic of New York City.<sup>1</sup> The present report deals with an analysis of some of the data accumulated in the twenty-seven months of the clinic's existence. This includes data on the prevalence of cardiac abnormalities and organic heart disease among adolescent school children. The problems bearing on the school child with heart disease, including medical supervision and early diagnosis, are discussed. In the period between Oct. 1, 1930, and Dec. 31, 1932, 166,152 children applied for working certificates in New York City. Of that number only 109,964 could be included in this analysis, because the children diagnosed as having cardiac abnormalities among the remaining 56,188 were not referred to the clinic for complete cardiac study. The great majority of these children were in the age group between 14 and 17 years and approximately 2 per cent were between the ages of 12 and 14 years. The children of the latter age group were boys who applied for newsboy badges and bootblack permits, to enable them to work after school hours.

The children in this study differ in two respects from those in similar surveys.<sup>2</sup> They are older and the age limits are narrower. The previously reported studies almost invariably cover the complete range of elementary school age, from 6 to 14 years, whereas the children in this study are almost entirely in the adolescent age group. Their economic status is another pos-

TABLE 1—Prevalence of Organic Heart Disease and Cardiac Abnormality Among School Children Applying for Working Papers from Oct. 1, 1930, to Dec. 31, 1932

Total number examined for working papers	Number	Per Cent
Total number included in present study	109,964	100.0
Children with suspected cardiac abnormality referred for diagnosis	1,432	1.3
Children examined in clinic	1,215	100.0
Diagnosed noneardiac	54	4.5
Diagnosed E	557	45.8
Diagnosed F	4	0.3
Diagnosed E and F	72	5.9
Diagnosed organic	528	43.5
Estimated organic in 1,432	622	43.5
Estimated organic in 109,964	622	0.57
Estimated proportion in general adolescent population		0.9

sible difference. Since these children enter industry prematurely, it would seem reasonable to assume that many come from poverty-stricken homes. These two factors—the age and the economic status—influence the results of this analysis and will be considered later.

### PREVALENCE OF CARDIAC ABNORMALITIES

Of the 109,964 children examined, 1,432, or 1.3 per cent, were referred to the cardiac clinic because of cardiac abnormalities. For lack of better terminology, the word "abnormality" is used to cover all the conditions for which the children were referred to the cardiac clinic, such as murmurs, cardiac enlargement, unusual arrhythmias and tachycardia. It is probable that many of these conditions are not indicative of abnormal hearts. On the other hand there are very few studies of such conditions in which the observations have been long continued, and the question of the significance of these symptoms is therefore unsettled. An incidence of 1.3 per cent for the prevalence of cardiac abnormalities is somewhat lower than the incidence of 1.9 per cent found in Boston by Robey.<sup>2a</sup> It is difficult, however, to evaluate this difference, since wide variations were reported by Baker,<sup>3</sup> who analyzed the physical records of the younger school children of New York City examined during the five years from 1915 to 1920. The minimum number of examinations in any one year was 243,416, the maximum was 328,190. Despite this large number, the reported incidence to "cardiac defect" varied between from 1.3 per cent to 1.9 per cent.

The studies by Robey<sup>2a</sup> and Baker<sup>3</sup> included children considerably younger than those of our study. A point of interest in their analyses is the prevalence of organic heart disease in the different age groups. In the Boston study<sup>2a</sup> organic heart disease was twice as

W. Department of Health Diagnostic Cardiac Clinic of New York City. *New York State J. Med.* 34: May 15 1934.

prevalent in the age group from 11 to 15 years as it was in the age group from 6 to 10 years. Baker<sup>3</sup> showed a similar age distribution, varying from 0.55 per cent incidence in the 6 to 8 year old group to 1.4 per cent in the 12 to 14 age group. Other investigators<sup>6</sup> have supported these observations.

The facts that organic heart disease increases in the older age groups and that the prevalence of cardiac abnormalities remains approximately the same throughout childhood suggest several possibilities for the young children who have such abnormalities: 1 Their abnormalities are transient. This is the general opinion. 2 The abnormalities are early manifestations of organic heart disease, which becomes more evident with time. This possibility is suggested by the study of Fineberg and Steuer.<sup>6</sup> 3 Cardiac abnormalities predispose to rheumatic carditis and organic heart disease.

This interesting phase of the problem can be answered only by following for a number of years a group of children who have so-called functional abnormalities. It is hoped that some light will be thrown on this problem by a study now being conducted at this clinic of a young group of children.

#### PREVALENCE OF ORGANIC HEART DISEASE

Of the 1,432 children referred to the cardiac clinic, 1,215 were completely studied. Of these, 528, or 43.5 per cent, were diagnosed as having organic heart disease. Assuming the same percentage of heart disease among the unexamined group, we estimated that the number among the 1,432 referred children would be 622, or 0.57 per cent, of the entire group of 109,964. This incidence is lower than that found in most surveys, except in the careful study made in Boston,<sup>2a</sup> where the prevalence of organic heart disease among 119,337 school children between the ages of 6 and 15 years was 0.52 per cent. This excluded, however, 265 doubtful cases. A similar study in New York City by Halsey<sup>2b</sup> revealed an incidence of 0.5 per cent.

The reported percentages of organic heart disease among unselected school children vary from the low incidence found in New York<sup>2b</sup> to 4 per cent in Rochester.<sup>2c</sup> The majority of the surveys show a prevalence under 1 per cent. A study by the Metropolitan Life Insurance Company<sup>2d</sup> among a comparable but smaller group of employed boys between the ages of 14 and 17 years revealed 1.6 per cent with organic heart conditions. In another study of 1,000 newsboys between the ages of 10½ and 18 years<sup>6a</sup> the percentage was 1.5.

The low prevalence of organic heart disease among the children of this study was of interest because the children were older and they came from a poorer class than those of the general school population. Both of these factors should favor a higher occurrence rate of organic heart disease. Because the group is older, it has been exposed longer to infection and it should embrace a larger number who have had rheumatic fever. In the Boston study<sup>2a</sup> there were 247 children with organic heart disease in the age group 11-15 as against 112 in the age group 6-10. A similar relation-

ship was found in the study at Philadelphia,<sup>2a</sup> where the prevalence among the age group between 6 and 14 years was 0.69 per cent, as against 1.1 per cent in the age group from 12 to 18 years. On this point, Baker's study<sup>3</sup> showed greater prevalence of heart disease in the succeeding age groups from 6 to 14 years, ranging from 0.6 per cent in the children of 6 years to 1.4 per cent in the oldest group.

The factor of poverty is mentioned, since it is generally accepted, both here and abroad, that rheumatic fever is more prevalent among the poor. Paul,<sup>7</sup> in summarizing this question, says "The data on social conditions as a predisposing factor in rheumatic fever seem to indicate that the incidence of the disease, particularly in childhood, is considerably more common among poorer people, although there is some question as to whether this applies to the most destitute or not."

In spite of these facts, this survey showed an unusually low incidence of organic heart disease. The explanation for the difference between the results of this and other reported surveys seems to be in the thoroughness of the examinations and the criteria for diagnosing organic heart disease. When examinations are carefully made, a lower incidence is found. Thus, in the survey at Boston,<sup>2a</sup> made by special examiners, an incidence of 0.52 per cent was found. In the study by Halsey,<sup>2b</sup> in which the children were examined at cardiac clinics, an incidence of 0.5 per cent was reported. In a study of cardiac classes in New York City,<sup>8</sup> also conducted by cardiac clinics, the incidence was 0.7 per cent. In the same group of children the incidence obtained from the records of the school physicians was 1.4 per cent, nearly twice that of the figure from the cardiac clinic. In a careful study at Philadelphia,<sup>2a</sup> which included high school children, the reported incidence of organic heart disease was 0.9 per cent. To our knowledge, in no previously reported survey, has the cardiac examination been so complete for every suspected child. In every instance of cardiac abnormality a complete history, physical examination, teleoroentgenogram and electrocardiogram were obtained. Each child was examined in the upright and in the recumbent position, and after exercise.

The criteria for cardiac diagnosis of the Heart Committee of the New York Tuberculosis and Health Association were followed. It is thought, therefore, that the diagnoses were made with a minimum of error and that the reported incidence of organic heart disease in this group is very close to the facts. It is evident that this incidence does not represent the prevalence of the disease in the general adolescent population. There must be some who, because they know they have heart disease, do not apply for working papers, and others who are confined to bed at home or in hospitals. It is obviously impossible to determine the size of this group and it can be estimated only roughly. The ratio found in the Boston study<sup>2a</sup> of the number confined to hospitals to the number attending schools, brings the total number with organic heart disease to 781, or 0.7 per cent. This still fails to include ambulatory patients who are too ill to apply for working papers and those who are sick at home, classes 2B and 3. It is probable that the number of those ill at home is greater than that of those in the hospitals. This statement is borne out by the figures from the borough of Kensington, England,<sup>7</sup>

where rheumatic fever is a reportable disease, and also by the report of the Committee on the Costs of Medical Care,<sup>9</sup> which showed a ratio of only 70.8 hospitalized cases per thousand illnesses of all types. If the figures from the borough of Kensington are applied to our study, the incidence would be increased to approximately 0.9 per cent. This, of course, is only a rough estimation.

#### THE ETIOLOGIC CLASSIFICATIONS

When the cases in this study are analyzed according to etiologic classifications (table 2), certain interesting facts become apparent. It will be noted that under the term "unknown etiology" there are included an unusually large number of cases. From this group are excluded the ones with a history of rheumatic fever, joint pains or chorea. These cases were all, however, of the acquired type of heart disease, with the lesions characteristic of rheumatic valvulitis. Whether they were in part due to infections not included in the rheumatic group or whether most of them presented rheumatic carditis unattended by other manifestations of rheumatic fever, as Wyckoff and Lingg<sup>10</sup> suggest, could not be ascertained. If the rheumatic and unknown groups of our study are combined, a total incidence of 91.3 per cent is obtained (table 2). This compares well with the similar etiologic groups of the studies by Wilson, Lingg and Croxford,<sup>11</sup> in which the incidence of the rheumatic and unknown groups totaled 88 per cent, and with the study by Wyckoff and Lingg,<sup>10</sup> in which the combined incidence of the two etiologic types in the age group from 10 to 19 years, was 94.5 per cent. The rheumatic groups in each of these studies included more than 80 per cent of the cases. It is probable that the unknown group in our study includes many patients who were rheumatic. The large size of this group seems explainable by the fact that this was a study of an unselected class of children, whereas the studies of Wyckoff and Lingg<sup>10</sup> and Wilson, Lingg and Croxford<sup>11</sup> were of clinic patients who in many instances came directly from hospitals, following attacks of rheumatic polyarthritis or chorea.

TABLE 2—Classification of Organic Heart Disease Found Among School Children at the Diagnostic Cardiac Clinic

Etiologic Classification	Number	Per Cent
Rheumatic	231	43.7
Unknown	251	47.5
Congenital	42	8.0
Chest deformity	2	0.4
Hypertension	2	0.4
Total	528	100.0
Functional Classification		
Class I	386	73.1
Class IIa	136	25.8
Class IIb	6	1.1
Total	528	100.0

Surveys among the general school population,<sup>11</sup> on the other hand, seem to indicate that in a large percentage of cases carditis is the first and only manifestation of rheumatic fever. In Robey's study,<sup>12</sup> only 29.6 per cent of the cases gave a history of chorea,

rheumatic fever or both. Richter<sup>11</sup> found 39.5 per cent, and she includes those with histories of growing pains, arthritic pains, tonsillitis or unexplained fever. Only 19.7 per cent of the patients in our study gave histories of rheumatic fever or chorea. The incidence of congenital abnormalities was 8.0 per cent. This is in fair agreement with the reports of other studies<sup>12</sup> excepting that of Richter,<sup>11</sup> who reported the high incidence of 33.5 per cent of congenital heart disease in the survey at San Francisco.

#### ORGANIC HEART DISEASE FIRST DISCOVERED AT THE CLINIC

The large number of children with organic heart disease first discovered at this clinic is of unusual interest. Thirty and nine-tenths per cent of the total number of patients learned of their heart disease for

TABLE 3—Number and Percentage of Children with Organic Heart Disease Classified According to Medical Supervision at the Time of Their Examination at the Diagnostic Cardiac Clinic

Type of Supervision	Number	Per Cent
Under medical supervision	243	46.0
Private physician	128	24.2
Clinic	115	21.8
Not under medical supervision	285	54.0
Condition previously known	122	23.1
Condition first discovered in clinic	163	30.9
Total	528	100.0

the first time. Among these 163 children, only forty-two gave histories of joint pains, polyarthritis or chorea. A large majority of the cases, 74.2 per cent, were therefore included in the unknown group. When carditis occurred, it was in a form that did not incapacitate the child and therefore remained unnoticed. Obviously, none of these children are under medical supervision and all enjoy unrestricted physical activity.

One cannot help being impressed with the importance of this group. It constitutes almost one third of the total number of children with organic heart disease in the adolescent employed population. In these children heart disease develops while they are carrying on their regular school activities. The condition is not heralded by inflamed joints or choreiform movements, and it escapes notice until it is discovered during a routine examination or until late in the disease when cardiac symptoms bring the patient to the physician.

#### MEDICAL SUPERVISION

Of the children with organic heart disease, 46.0 per cent were under medical supervision (table 3). This small figure is due, for the most part, to the fact that almost one third of the children did not know that they had organic heart disease. Of those who had knowledge of their condition, 67 per cent were receiving medical care. This seems to indicate that there is no unwillingness on the part of the children to obtain medical supervision. It is ignorance of the existence of the disease that is the cause of the lack of medical supervision. This fact stresses the need for yearly examinations in order to diagnose heart disease early and bring the children under medical care.

#### AGES AT WHICH ORGANIC HEART DISEASE DEVELOPS

This analysis seems to support the evidence of Wilson, Lingg and Croxford,<sup>11</sup> Mackie<sup>13</sup> and other

<sup>9</sup> The Incidence of Illness and the Receipt and Costs of Medical Care Among Representative Families. Publication 26. The Committee on the Costs of Medical Care, appendixes, p. 285.

<sup>10</sup> Wyckoff, John and Lingg, Claire. Statistical Studies Bearing on Problems in the Classification of Heart Diseases. II. Etiology in Organic Heart Diseases. *Am Heart J* 1: 446 (April) 1926.

<sup>11</sup> Robey, Richter, Ina M. Incidence and Variety of Heart Disease in School Children of San Francisco. *J A M A* 97: 1060 (Oct 10) 1931.

<sup>12</sup> Robey, Cahan, Wilson, Lingg and Croxford.

observers<sup>13</sup> that rheumatic heart disease develops during the school age rather than during the preschool period. In the New York schools, all children are examined by the school physician on entering at the age of 6 years unless they bring records of examinations from their private physicians. When a child is found to have a cardiac condition, it is recorded on the health card and the parents are notified. There is evidence that the tendency among the school physicians is to include in the cardiac group a large number who do not have organic heart disease.

TABLE 4—*Known Duration of Heart Disease Among 528 Children*

	First Discovered at Clinic	1-3 Yrs	4-6 Yrs	7-9 Yrs	10-12 Yrs	13-16 Yrs	Since Birth	In definite	Total
Number of children	163	130	93	62	30	15	12	18	528

It is therefore most unlikely that the organic cases found in the present study would have been missed by the school physician had the lesions existed when the children first entered school. This point is borne out also by the figures in table 4, which gives the duration of heart disease as obtained from the histories. Obviously, these figures cannot coincide with the actual duration of the cardiac lesion, which undoubtedly is longer. There were 410 children (84.3 per cent) with acquired heart disease who first learned of their condition after the age of 7 years. This is in fair agreement with the statement of Wilson, Lingg and Crawford,<sup>14</sup> that in 80 per cent of the cases rheumatic heart disease develops after the age of 6 years. Robey's<sup>2a</sup> study also corroborates these results. He found more than twice as many children with organic heart disease in the age group between 11 and 15 years as in the age group between 6 and 10 years. These results are in disagreement with Baker's<sup>3</sup> interpretation of her studies, when she states that chronic diseases, including heart disease, "remain at about the same level throughout school life." It also contradicts a similar conclusion in the special reports on cardiac classes in New York City.<sup>8</sup> "In rare instances only do these heart defects develop during the elementary school period."

#### DISCREPANCIES IN DIAGNOSIS BETWEEN THIS CLINIC, SCHOOL PHYSICIANS AND PRIVATE PHYSICIANS

Because of the importance, from the aspect of public health, of accurate and early diagnosis of cardiac disease, an important question arises as to the effectiveness of the customary examinations by school or private physicians. It is therefore of interest to compare the results of this study, in which all necessary facilities for specialized diagnosis were available, with records from groups examined by medical inspectors or private physicians.

An effort was made to ascertain how frequently the diagnoses made at this clinic varied from those made by the school physician or by the private physician. All children who came to the clinic were referred with diagnoses made by medical examiners. These were often so inadequate, however, that it was found impossible to use them for the study. An analysis was made of our statistics, of those from the records of children examined during the ten months before the clinic was established and of those from the records of children

examined during the summer months of 1931 and 1932. In the latter group 42,278 children were examined by school physicians but were not referred to the cardiac clinic. Organic heart disease was the diagnosis in 494 (1.2 per cent) of the children. In 1930, during the ten months period before the clinic was organized, 84,712 children were examined and an incidence of 1.4 per cent organic heart disease was found. These figures compare well with the prevalence of cardiac abnormalities obtained in our study, which is 1.3 per cent, and suggest that every cardiac abnormality was considered organic heart disease. It was impossible to compare the clinic diagnoses with those made by private physicians. Baker<sup>4a</sup> has shown, however, that the diagnosis by the private physician shows the same tendency toward indiscriminate. In an analysis of 27,854 records of physical examinations made by private physicians, of children entering the public schools, an incidence of 1.6 per cent of cardiac defect was found. This incidence was almost identical with that shown by the records of the medical inspectors.

It will be noted that seventy-seven children who were diagnosed at this clinic as class E (table 5) had had their activities restricted by private physicians, some for many years. In general, the school physicians and the private physicians diagnosed many more cases as "organic cardiacs" than we did. If the prevalence of organic heart disease as estimated by this clinic is correct, more than one half of the children who were denied working papers before this clinic existed were unjustifiably deprived of the right to work. This point is brought out merely to emphasize the necessity for

TABLE 5—*Duration of Restriction of Activity on Medical Advice Among Seventy-Seven Children in Class E*

Number of children	Number of Years Restricted				Total
	1-3	4-6	7-14	Indefinite	
	44	12	15	6	77

better facilities for cardiac diagnosis, particularly when the question of employment is involved. A well organized and equipped clinic should help to eliminate this injustice and should pay for itself by the earning powers of those who otherwise would be deprived of work.

#### ORGANIC HEART DISEASE COMPARED WITH OTHER IMPORTANT DEFECTS

Some idea of the importance of heart disease among adolescent children may be obtained through a comparison between the prevalence of cardiac disease and other serious defects for which children were refused working certificates. From October 1930 to December 1932, among the total 166,152 children examined, forty-two were permanently refused certificates for the following conditions: chronic pulmonary tuberculosis, five; deafness, twenty; chorea, four; serious orthopedic defects, ten; trachoma, one; and irremediable defective vision, two.

When 0.57 per cent was used as the incidence of organic heart disease, 930 of the total number were estimated to have organic heart disease. Thus, it is seen that heart disease as an important defect far outranks the others.

#### SUMMARY

1. In New York City during the twenty-seven months from Oct. 1, 1930, to Dec. 31, 1932, 166,152

children between the ages of 14 and 17 years were examined for working papers

2 A diagnosis of cardiac abnormality was made in 1,432 (13 per cent) of 109,964 of the total number, and the patients were referred to the diagnostic cardiac clinic for cardiac study. This study included in each case a complete history, physical examination by a cardiologist, an electrocardiogram, a teleroentgenogram and urinalysis

3 A complete study was made of 1,215 of the cases, and 528 were found to present organic heart disease. This was estimated to indicate an incidence of 0.57 per cent of the total number

4 The estimated incidence of organic heart disease in the general adolescent population is 0.9 per cent

5 An unusually large number (47.5 per cent) of the children with organic heart disease did not give a history of rheumatic polyarthritis, chorea or joint pains and were included in the group in which the etiology of the heart disease was unknown. All of these showed the rheumatic valvulitis which characterizes acquired heart disease

6 Of the total number with organic heart disease, 163 children (30.9 per cent) learned of their condition for the first time at this clinic. Of this group, 74.2 per cent are classified as of unknown etiology. It is believed that many of these cases remain undiscovered because the only rheumatic manifestation was carditis and that the lesion had developed insidiously without incapacitating the child or interrupting its school activities

7 A diagnosis of a functional condition (abnormal signs) or potential heart disease was made in 633 children (52 per cent) who were referred because of a cardiac abnormality. In fifty-four (4.5 per cent) there were no abnormal signs or history of rheumatism. The school physician and the private practitioner show the tendency to include in the organic group many who have no evidence of organic heart disease

8 Two hundred and eighty-five children (54.0 per cent) were not under medical supervision. Of those who received medical care, 128 (52.7 per cent) were under the care of private physicians. The other 47.3 per cent were receiving care at a cardiac or general medical clinic

9 This study seems to indicate that acquired heart disease develops in children of school age

10 In the adolescent school population in New York City, heart disease far outnumbers all other serious defects

#### CONCLUSION

The prevalence of organic heart disease among the adolescent population of New York City is estimated at 0.9 per cent. A large number of children with organic heart disease, approximately one third of the total, do not know that they have the disease and are not under medical supervision. The medical facilities of the department of health are entirely inadequate from the point of view of the cardiac child in school.

The greater degree of accuracy in cardiac diagnosis rendered possible by the facilities of the diagnostic cardiac clinic has decreased by more than 50 per cent the number of children who are refused working certificates. The correction of this injustice and the systematic procedure to obtain medical supervision for all of those who have organic heart disease have justified the existence of this clinic

75 East Fifty-Fifth Street

## AGRANULOCYTIC LEUKOPENIA

REPORT OF A CASE SUCCESSFULLY TREATED WITH  
X-RAYS AND SOME OBSERVATIONS ON THE  
EFFECT OF AMIDOPYRINE

JULIEN E. BENJAMIN, M.D.  
AND  
JOSEPH B. BIEDERMAN, M.D.

CINCINNATI

As early as 1931 Kracke<sup>1</sup> reported severe and repeated attacks of agranulocytosis in an individual using large amounts of coal tar derivatives. He likewise suggested that the benzene chain contained in the drugs might act as a powerful leukocytic depressant. More recently, he<sup>2</sup> has called particular attention to this fact in a review of nine cases. Madison and Squier<sup>3</sup> directly accuse certain of the benzene derivatives as causative factors of granulopenia in a large number of cases.

The following case is reported because it adds to the evidence that severe granulopenia may follow the administration of drugs of this group.

#### REPORT OF CASE

*History*—A white woman, aged 48, a nurse, while on duty suddenly experienced the prodromal symptoms of a grippal infection, characterized by headache, chills, exhaustion and sore throat. After two or three days of self medication (?) her condition grew worse and she was admitted to the Jewish Hospital, Jan. 13, 1931, extremely ill. The face was flushed, the eyes were dull and she could not raise her voice above a whisper.

The temperature was 103 F., the respiration rate was 20, and the pulse rate was 110. The breath was fetid, and the soft and hard palates were dark red and of a granular appearance. The physical examination was otherwise negative. The laboratory reported a slight trace of albumin and an occasional finely granular cast in the urine. The blood picture was as follows: The red blood cell and hemoglobin were normal, the total white cell count was 1,700, the polymorphonuclears were 8 per cent, the lymphocytes were 68 per cent, the transitionals were 22 per cent, and the large mononuclears were 2 per cent.

The patient was immediately given high voltage roentgen therapy over the long bones by Dr. Samuel Brown, according to the dosage in the accompanying table.

*Dosage of Roentgen Therapy Given*

Date	Region	Milli amperes	Filter	Time, Minutes	Kilo volts	Distance Inches
1/16/31	Right leg	5	3 mm aluminum	5	90	12
1/17/31	Right arm	5	3 mm aluminum	5	90	12
1/21/31	Left arm	5	3 mm aluminum	5	90	12

The effect of these treatments was most impressive. There was a fairly prompt alleviation of the severe aches, the fever gradually receded, and the white cell count altered as follows: January 20 the total white cell count was 1,050, the polymorphonuclears were 41 per cent, the lymphocytes were 38 per cent, the transitionals were 12 per cent and the large mononuclears were 9 per cent. January 25 the total white count was 2,600, the polymorphonuclears were 61.5 per cent, the lymphocytes were 33 per cent, the transitionals were 3.5 per cent and the large mononuclears were 2 per cent.

The effect of roentgen treatment on the white cell count is shown in chart 1.

Read before the Academy of Medicine May 7, 1934.

1. Kracke R. R. *Am. J. Clin. Path.* 1:385 (Sept.) 1931.

2. Kracke R. R. *Am. J. Clin. Path.* 2:11 (Jan.) 1932.

3. Madison F. W. and Squier T. L. *Primary Granulocytopenia After Administration of Benzene Chain Derivatives* *J. A. M. A.* 101:2076 (Dec. 23) 1933.

**Course of Illness**—During the rest of the year 1931 and the first half of 1932, the patient had several attacks of chills, fever and sore throat, during which time the white cell count was lowered in the characteristic manner. In each instance one of the coal tar derivatives (?) was taken. The attacks were mild, with the exception of one in which there was a severe stomatitis followed by extensive sloughing of the soft tissues. The white cell count on this occasion was 850, with 91 per cent lymphocytes and 9 per cent polymorphonuclears. This attack was amenable to roentgen therapy.

For the past seven months the patient has remained well. On April 18, 1934, the blood picture was as follows: The white blood cell count was 3,700, the polymorphonuclears were

Chart 1—The variations in the total white and differential blood counts during two attacks of agranulocytosis. The effect of roentgen treatments is shown.

69 per cent, the lymphocytes were 22 per cent, the large mononuclears were 6 per cent and the transitionals were 3 per cent. The white blood cell count rarely exceeded 4,000.

**Effect of Administration of Amidopyrine**—April 19, the patient agreed to take 10 grains (0.648 Gm) of amidopyrine, a drug she probably had taken frequently. At 4 p. m., exactly twenty-four hours after the preceding cell count and three hours after the ingestion of the drug, the count had fallen to the levels shown in chart 2. The total white cell count was 1,700, the polymorphonuclears were 50 per cent, the lymphocytes were 44 per cent, the large mononuclears were 4 per cent and the transitionals were 2 per cent.

The patient stated that one hour after she took the amidopyrine a headache and backache developed and she was nauseated. A mild sore throat gradually developed and when she was seen the temperature was 99.2.

April 20, exactly twenty-four hours after she took the amidopyrine, the white blood count was as follows: The total count was 1,000, the polymorphonuclears were 56 per cent, the large mononuclears were 8 per cent, and the transitionals were 11 per cent. The symptoms at this time were exaggerated and the patient was considerably prostrated. There was also swelling of the gums.

April 21, forty-eight hours after she took the drug, the white cell count tended to return toward the normal level. The total count was 2,500, the polymorphonuclears were 39 per cent, the lymphocytes were 49 per cent, the large mononuclears were 4 per cent and transitionals were 8 per cent. The patient's general condition was unchanged although the throat symptoms were somewhat worse.

April 22, seventy-two hours after the initial dose of amidopyrine, the blood cell count and the general condition were practically unchanged.

April 23, four days after she took the drug, the white cell count was 4,400, the polymorphonuclears were 53 per cent, the lymphocytes were 39 per cent, the large mononuclears were 3 per cent and the transitionals were 5 per cent. There was general improvement on the part of the patient. Subsequent cell counts have been normal.

April 27, the white cell count was 5,200, the polymorphonuclears were 66 per cent, the lymphocytes were 28 per cent, the large mononuclears were 3 per cent and the transitionals were 3 per cent.

The patient was given 10 grains (0.65 Gm) of acetylsalicylic acid. Studies of the blood demonstrated that the white count was unaffected and the patient's condition remained satisfactory.

April 30, the white cell count was 4,700, the polymorphonuclears were 54 per cent, the lymphocytes were 38 per cent, the large mononuclears were 4 per cent and the transitionals were 4 per cent.

The patient was given 2 grains (0.13 Gm) of alurate (allyl iso-propyl-barbituric acid) and the effect on the blood was studied in a similar manner, with negative results.

**Allergy Tests**—In an attempt to determine whether the reaction of the hematopoietic organs to these drugs was of an atopic nature, as suggested by Pepper,<sup>4</sup> or was the result of a hypersensitivity as is hinted at by Madison and Squier,<sup>5</sup> the patient was subjected to the following procedure.

After it had been determined that there was no instance of an allergic phenomenon in her personal or family history, skin tests were made with fifty-four common foods by the intracutaneous method.<sup>6</sup> The total nitrogen content of the testing extracts was 0.05 mg per cubic centimeter. The patient reacted positively to tea, parsnips, lemons, barley, pecans and chicken. Given a test meal of these ingredients, the white blood count decreased only slightly and the patient experienced no ill effects. The patient was next tested (patch method) with acetylsalicylic acid and amidopyrine, the results were negative.

Following this she was given intracutaneous tests with acetylsalicylic acid and amidopyrine, the results were negative. Passive transfer tests<sup>6</sup> were now made, in which 0.1 cc of the patient's serum was injected into the skin of a normal subject. This was followed forty-eight hours later by the injection into these sites on the normal subject of test solutions of acetylsalicylic acid and of amidopyrine. No reaction resulted, indicating the absence of reagins for acetylsalicylic acid and amidopyrine in the blood of the patient.

#### COMMENT

The granulopenia, at least in the case here reported, was not of an atopic nature but more in the nature of a drug hypersensitivity with the hematopoietic system acting as the shock organ.

Chart 2—The effect of the administration of 10 grains (0.648 Gm) of amidopyrine during a remission that has lasted eighteen months.

#### SUMMARY

- 1 A case of agranulocytosis herewith reported was apparently amenable to high voltage roentgen therapy.
- 2 During a period of good health the patient was given 10 grains (0.65 Gm) of amidopyrine under control. This produced all the symptoms of agranulopenia within forty-eight hours.

<sup>5</sup> Cooke R. A. Laryngoscope 25 108 1915.  
<sup>6</sup> Walker M. and Kramer S. D. J Immunology 10 835 (Sept) 1925.

3 The administration of acetylsalicylic and allyl-isopropyl-barbituric acids caused no unfavorable symptoms

4 Intracutaneous, patch and passive transfer tests gave negative reactions

5 In this patient the effect of imidopyrine was one of hypersensitivity to the drug and was not of an atopic nature

## NECROBIOSIS LIPOIDICA DIABETICORUM (URBACH)

DERMATITIS ATROPHICANS LIPOIDES DIABETICA  
(OPPENHEIM)

HENRY E MICHELSON, MD

AND

CARL W LAYMON, MD

MINNEAPOLIS

Until 1928 the only recognized cutaneous change in diabetes mellitus which had any possible diagnostic value was xanthoma diabeticorum. In that year Oppenheim<sup>1</sup> observed and described a condition which had a well defined clinical appearance and occurred only in diabetes. He called the condition dermatitis atrophicans lipoides. Urbach<sup>2</sup> reported the study of a similar case in 1932. He entitled the condition necrobiosis lipoidica diabeticorum. Since the report of these first two cases, other examples have been recorded by Galewsky,<sup>3</sup> Gottron,<sup>4</sup> Balbi<sup>5</sup> and Zeisler and Caro.<sup>6</sup> There is, as yet, no official international nomenclature for this condition. Because the majority of the observers have used the name suggested by Urbach, we have adopted it for the sake of convenience.

### LITERATURE

Urbach<sup>2a</sup> wrote the first formal article on necrobiosis lipoidica diabeticorum and since then has reviewed the condition in other contributions.<sup>7</sup> He regarded the disease as a metabolic dermatosis, related to the disturbances of lipid metabolism as well as to diabetes. His paper reported the case of a woman, aged 44, who had been treated for severe diabetes mellitus since 1926. In 1928 a cutaneous lesion appeared on the calf of the left leg, and a year later two similar lesions were noted on the left ankle. At the time of examination there were numerous lesions of the lower extremities in various stages of development. The more recent lesions were papules, while the larger, older ones were plaques.

Although Oppenheim had observed his patient since 1928, the complete study of the case was not published until October 1932.<sup>1a</sup> The patient had been treated for diabetes by Professor Stejskal for several years, and the skin changes had appeared one year after the onset of the diabetes. At the time of the first examination in 1928 there were cutaneous lesions on the anterior and the posterior surfaces of the lower extremities, the arms and the trunk. At this time the buttocks, palms and soles did not show the lesion. In 1932 these areas as well as the face were affected. The early lesions were papules and the later ones were plaques, identical with the lesions Urbach had observed in his patient.

Galewsky<sup>3</sup> presented the third case of this skin condition and showed moulages and microscopic sections at the meeting of the Dresden Dermatologic Association in October 1932. A complete study of the case has not been reported.

The fourth case was shown by Gottron<sup>4</sup> before the Berlin Dermatologic Society in December 1932. The patient was a woman, aged 37, who had had diabetes since 1927. Skin lesions had developed gradually on the lower extremities for four years, in spite of the fact that the diabetes had improved. Numerous new lesions had appeared within the past year which superficially resembled morphea. The total cholesterol, cholesterol esters and fatty acids in the blood were abnormally high.

Balbi's<sup>5</sup> patient, a man, aged 55, presented a severe type of the disease. The lesions clinically were similar to those in the previous cases, except that many ended in central ulcerations.

The fifth case was that of a man, aged 27, presented by Zeisler and Caro<sup>6</sup> to the American Dermatological

TABLE 1—Classification of Lipoids

General Group	Individual Example	General Chemical Composition
I True neutral fat (glycerine esters)		Glycerin and fatty acid
II Cholesterol and cholesterol esters		Cholesterol and fatty acid
III Lipids		
1 Phosphatides		
a Unsaturated	Lecithin and cephalin	Organic base + glycerin phosphoric acid + fatty acid
b Saturated	Sphingomyelin	Organic base + phosphoric acid + fatty acid
2 Cerebrosides	Phrenasin and keratin	Organic base + galactose + fatty acid

Association in Chicago in 1933. Since then, these observers have seen another case in a white woman, aged 72.

As far as we are able to determine, the case we discuss in this paper is the seventh recorded in the literature. The patient was younger than those in previous reports. Before the case is reported it is important to review briefly the classification of lipoids and the cutaneous lipoidoses and to give a few facts about the histochemistry of these fatty substances.

During the past twenty-five years the term lipoid has appeared frequently in medical literature. Although it is beyond the scope of the dermatologist to go into the detailed chemistry of the lipoids, it is advantageous to consider briefly the substances that are included in this group and the diseases in which they play an important role. Lipoid is a generic name applied to all those substances in the organism which in their general chemical and physical properties, and especially

in their solubilities, resemble the fats. The classification<sup>8</sup> of lipoids is shown in table 1.

The term lipid, as adopted at the International Congress of Chemistry in 1923,<sup>9a</sup> was intended to designate only phosphatides and cerebrosides, although Schaaf<sup>9</sup> and Wile<sup>10</sup> have since applied it to the total of all fat-like components of tissues or blood that are soluble in ether and alcohol, in other words, total lipoids.

Although cholesterol, one of the sterol group of alcohols, is related to the other lipoids only in its solu-

phatide (lecithin), 200-250, total lipoids (lipid-Schaaf), 700-800.

Lipoids are found normally in all living matter and are therefore considered as essential components of protoplasm. Their concentration and nature may vary in different tissues, and their exact function is not definitely known. They may also appear abnormally in the skin, mucous membranes, blood, bones and internal viscera, forming the basis for many distinctly varied diseases. In this paper the lipoidoses that are entirely internal in their localization, such as Gaucher's and Niemann-Pick's disease, are not considered. Urbach's classification of the cutaneous lipoidoses is shown in table 2.

TABLE 2—Classification of the Cutaneous Lipoidoses (Urbach)\*

Generalized Types		
Type	Chief Features	Lipoid
Xanthelasma (infiltration type)	Palpebral (essential and secondary types) includes Hand-Schüller-Christian disease, foam and giant cells microscopically	Cholesterol and cholesterol esters (intracellular)
Extracellular cholesterinosis (Kerl-Urbach)	Multiple reddish brown papules and nodules, sometimes resemble erythema multiforme, located on extremities, trunk and mucosae, extracellular lipid deposits especially as mantles around the vessels, no foam cells	Cholesterol and cholesterol esters (extracellular)
Hepatosplenomegalia, skin and mucous membrane lipoidosis (Burger-Grütz)	Yellow firm nodules on skin of face and extremities, mucous membrane lesions, spleen and liver greatly enlarged, lipemia, fundi increased phosphatides in blood, perivascular lipid mantles and intracellular and extracellular lipid granules	Phosphatides (intracellular and extracellular)
Lipoidproteinosis (Urbach-Wiethe)	A familial disease occurring in the course of latent diabetes, yellowish nodules on skin and mucosae, hyperkeratotic lesions on extremities, hoarseness (laryngeal involvement) usually since birth, no foam cells	Probably phosphatides joined to a protein
Localized Types		
Necrobiosis lipoidica diabetorum	Urbach states that in one sense this disease might be considered a generalized lipoidosis, since there is a hyperlipemia; however, the earliest symptom is the necrobiosis, and is the one on which the disease depends	Type of lipid not definitely established
Resorption xanthelasma	Due to local freeing of lipoids as in gummas and scars	Cholesterol and cholesterol esters (intracellular)
Lipoid degeneration of the elastin (Kreibich) or imbibile lipoid elastine (Urbach)	The process that occurs in sailors' skin and in cutis rhomboidalis nuchae	Type of lipid not definitely established

\* Internal lipoidoses (Gaucher's and Niemann-Pick's disease) not mentioned in this classification.

bility, it can be seen from the table that the other lipoids show common qualities in their chemical makeup. All of them contain fatty acids, and the same acid may be found in different lipoids. Glycerin is present in both neutral fat and unsaturated phosphatides, and similar organic bases occur in more than one lipid. (Choline occurs in both unsaturated and saturated phosphatides and cerebrosides.)

The normal values for plasma lipoids are: neutral fat, 100-250 mg per hundred cubic centimeters; fatty acids, 250-450; cholesterol and esters, 110-150; phos-

HISTOCHEMISTRY

It is generally accepted that the isolated, chemically pure, lipoids can be differentiated from one another by histochemical methods. This differentiation is accomplished by various lipid stains on formaldehyde-fixed tissue and by extraction of the lipoids by means of solvents such as acetone, ether and absolute alcohol. Histochemical methods, however, have only a relative value in differentiating the lipoids that may occur abnormally in the tissues. Kutschera-Aichberger<sup>8c</sup> has concluded, after exhaustive experimentation, that the color characteristics of a certain chemically pure isolated lipid cannot always be brought out in the same way in the tissues, where there is usually a mixture of lipoids and where the staining reactions can be influenced by substances in the cell protoplasm near the lipoids. A lipid that shows a definite staining property in the pure state can show a changed staining reaction or a lack of staining reaction in the tissues. Thus one cannot say positively that a definite lipid is present in the tissues because a color is obtained that coincides with the color obtained with the same stain on the same lipid in the pure state. Kutschera-Aichberger stated, furthermore, that until 1925, at least, lipid analysis had been greatly overrated. Balb<sup>5</sup> noted that Hueck maintained that precision with dif-

TABLE 3—Reactions for Lipoids

Reaction	Neutral Fat	Free Cholesterol	Cholesterol Esters	Phosphatides
Sudan III	Scarlet or orange red	Scarlet or orange red	Scarlet or orange red	Stain poorly (light yellow) if at all
Nile blue sulphate	Red	Blue violet	Blue violet	Blue violet
Claes	Unstained	Unstained	Unstained	Reddish yellow
Smith-Dietrich	Unstained	Unstained	Unstained	Blue black
Fischer	Used for the demonstration of fatty acids			
Schultz	Unstained	Unstained	Blue green	Unstained
Kossa	Stains calcium black			
Benda	Neutral normal fat red, necrotic fat green			
Digitalin	Negative	Precipitates	Negative	Negative
Double refraction	Absent	Slight	Positive	Slight

ferential staining and extraction methods is impossible and that Kaufmann-Lehmann believes that Sudan III is the only reliable lipid stain.

Thus it appears that a direct chemical analysis is necessary to ascertain the types of lipoids that are present in any given tissue. The reactions that have been determined for the lipoids in their pure states are shown in table 3.

Table 3 shows that double refraction is completely absent only in neutral fat, that cholesterol, cholesterol esters and neutral fat stain well, while the phosphatides stain poorly, if at all, with Sudan III, and that the

phosphatides are best stained with the Ciaccio and the Smith-Dietrich methods

Table 4 shows the results to be expected in fractional lipid extractions

Up to the present time the only reports of histochemical studies in necrobiosis lipoidica diabetorum have been those of Urbach and Balbi. For the sake of brevity, their results are shown schematically in table 5

The reddish brown obtained by staining with sudan III, and the reddish tint obtained with Nile blue sulphate, were suggestive of the presence of neutral fat, while the black given with Smith-Dietrich and the positive staining with Ciaccio indicated the presence, in part at least, of phosphatides. The lack of double

TABLE 4—Fractional Lipid Extractions

Solvent	Lipoids Extracted	Lipoids Not Extracted
Acetone	Neutral fat, cholesterol, ester, acetone soluble phosphatides, fatty acids	Unsaturated and saturated phosphatides and cerebrosides
Ether	Unsaturated phosphatides	Saturated phosphatides and cerebrosides
Absolute alcohol	Saturated phosphatides and cerebrosides	

refraction was against the presence of cholesterol esters, and the negative reaction to digitonin favored the absence of free cholesterol. The Schultz reaction for cholesterol was surprisingly positive in Balbi's case, but he was of the opinion that the digitonin reaction was the more reliable and the one to be accepted. Urbach likewise found the digitonin reaction negative. It is to be noted that in all cases in which two analogous reactions were done, Urbach and Balbi were in complete agreement.

In Balbi's case, a large part of the lipoids in the tissues were removed by acetone extraction, as proved by restaining with sudan III. Traces of reddish stain remained in some areas, however. After extraction with ether there were still traces of sudanophilic substances, but after extraction with absolute alcohol and benzene there was almost complete absence of substances staining with sudan III. In each extraction, the formaldehyde-fixed frozen sections were allowed to remain in the cold solvent for twenty-four hours and then were stained.

Balbi deduced from the results of the extractions that a large part of the lipoids in the tissues are to be grouped with neutral fat, cholesterol, cholesterol esters and acetone-soluble phosphatides, owing to the fact that they were extracted with acetone. From the staining reactions (digitonin negative, double refraction negative) it is natural to assume that most of the extracted lipid was neutral fat. Almost all the remaining lipid was extracted with ether, suggesting that it belonged to the group of unsaturated phosphatides. Balbi made these deductions reservedly but believed that the studies were at least an aid in determining the general groups to which the lipoids in question belonged.

#### CLINICAL FEATURES OF NECROBIOSIS LIPOIDICA DIABETICORUM

Both Urbach and Oppenheim have agreed that the earliest lesions are sharply bordered, distinctly elevated red papules from 1 to 3 mm in diameter, which may be capped by a slight scale and which do not disappear under glass pressure. Oppenheim has termed these lesions the first stage of the disease.

The well developed lesions, which may be considered representative, are round, oval or irregular plaques with well defined borders, of firm consistency, and having a smooth, glistening surface, which looks as if it were covered with a tightly stretched layer of cellophane. Oppenheim has noted that the lesions may assume the glazed appearance of lichen planus and has reported definite ringed lesions, violet at the periphery, followed by a yellow ring with a whitish center. The fully developed lesions appear to have a depressed center, with atrophy.

In all the recorded cases the color has been uniform. At first glance, one is immediately reminded of a xanthomatous lesion. There is a peculiar yellow tint which suggests this, but on more careful scrutiny one realizes that there is a difference in the color of the plaque at the center in contrast to its color at the periphery. The outer zone is a shade of violet, with a gradual transition to a lighter, more yellowish pink tone in the center. The surrounding skin is normal.

Many fine telangiectatic vessels trace over the surface of the plaque, which is usually smooth and without secretion. In Balbi's patient many of the lesions ulcerated.

Morphologically, the typical lesion, which Oppenheim has designated as the second stage of the disease, is simply a well defined plaque with an identifying color closely related in its general characteristics to the cutaneous xanthelasma.

Oppenheim has described a third stage, which he states is not shown in all cases. It is characterized by a definite deling of the center of the lesion, a more diffuse border, and a central grayish white scale.

Judging from the smaller number of cases that have been reported, the disease can occur at any age and in either sex. The extreme age limits have varied from 10 years in our patient to 72 years in one of the patients of Zeisler and Caro. The beginning is insidious and the course throughout is asymptomatic. The most common location is on the lower extremities, especially at the ankle region. The forearms are next in order of frequency, and lesions have been reported on the trunk, face, palms and soles.

#### REPORT OF CASES

CASE 1—History—K. D., a girl, aged 10 years, had been treated for diabetes for the past five years. Both dietary restrictions and from 25 to 35 units of insulin daily were required to control the disease. Under this regimen, growth and development had been normal. The first cutaneous lesion, which was at first thought to be a bruise, had appeared on the lateral surface of the right ankle about three years previously and had changed but little in size and appearance since it was first noticed. About eight months following the onset of the initial lesion a second one appeared on the calf of the right leg as a red pimple, resembling a mosquito bite. Later, this lesion became a plaque that spread peripherally and assumed characteristics identical with the older lesion except for the size.

Two new lesions had developed eight months before on the dorsum of each foot and could be palpated before they could be seen. They were lighter in color and smaller than the older ones but were duplicates in all other respects.

The eruption had remained asymptomatic throughout its course and there had been no other cutaneous lesions at any time. The mother, father, sister and brother of the patient were all living and well and free from cutaneous eruptions. No other member of the family had diabetes.

**Physical Examination**—The general physical examination was negative except for the condition of the skin. The eyes, ears, nose, throat, heart and lungs were apparently normal, and the liver and spleen were not palpable.

The entire eruption was confined to the lower extremities. The oldest lesion, which was situated on the lateral surface of the right ankle, was a sharply defined oval plaque, which measured 5 by 3.5 cm. It was scleroderma-like in consistency and covered by thin smooth epidermis, which appeared shiny and gave the impression of being atrophic. The yellowish violet in the central portion of the lesion deepened to a darker hue as the periphery was reached. Minute tortuous blood vessels passed through the thin surface covering.

The second lesion was a round plaque 2 cm in diameter, located on the posterolateral surface of the calf of the right leg. The details of this lesion were identical with those of the other plaque.

The two newest lesions, situated on the dorsum of each foot, measured 1.5 cm in diameter, were pink rather than violet, and were raised in barely perceptible manner above the surface or the surrounding skin. These lesions were less firm than the older ones and the atrophic, shiny appearance of the latter was lacking.

**Laboratory and Metabolic Data**—Urinalysis showed a specific gravity of 1.030, an acid reaction to litmus and an absence of albumin. The qualitative examination of the urine for sugar, Benedict's solution being used, was strongly positive on several occasions.

The routine examination of the blood showed hemoglobin, 81 per cent (Sahli), leukocytes, 7,150, neutrophils 46 per cent, eosinophils, 3 per cent, monocytes, 1 per cent, and lymphocytes, 50 per cent.

The Kolmer, Wassermann, and Kline blood tests were negative. The fasting blood sugar was 220 milligrams per hundred cubic centimeters (method of Folin). Other examinations of the blood plasma (method of Bloor) showed total cholesterol, 233 mg per hundred cubic centimeters of plasma, phosphatide (lecithin), 178 mg, and fatty acids, 428 mg.

**Microscopic Changes**—The biopsy was taken with a punch from the oldest lesion on the right ankle and was fixed in 10 per cent solution of formaldehyde. Frozen sections were made from part of the tissue and the remainder was embedded in paraffin and sectioned in the usual manner. We also had the privilege of examining the histologic sections from both of the cases of Drs. Zeisler and Caro.

The sections stained with hematoxylin and eosin showed a slight hyperkeratotic scale. All the layers of the epidermis were present. The basal layer was intact, although there was a definite but irregular increase of pigmentation. Aside from this, the epidermis was essentially normal.

Throughout the entire corium, the striking feature was the diffuse but patchy infiltration of localized collections of cells. It was arranged predominantly about the vessels but also pushed the collagen bundles aside, completely replacing them only in small areas. The collagen bundles were of irregular size and on cross section appeared to be swollen but the usual architecture and nuclei were present throughout except in the areas of heaviest infiltration. With higher magnification the infiltrate was seen to be made up of lymphocytes and fibroblasts. There were no plasma cells, giant cells, or polymorphonuclear leukocytes. One gained the impression from an examination of the infiltrate that the different foci of inflammation were of different ages. In certain areas the infiltrate consisted entirely of lymphocytes while in other areas there was a preponderance of fibroblasts, indicating an attempt at repair.

On a complete survey of the sections, necrotic areas were found in which the collagen appeared pale homogenized and

without nuclei. In and about these areas were the heaviest collections of lymphocytes and fibroblasts. They represented the necrobiotic foci described by Urbach and in almost all of them vessels were seen either in longitudinal or cross section. When the vessels were present, the intima was definitely swollen and proliferated, even to the point of occlusion of the lumen. However, no massive areas of necrosis were observed in any of the sections.

The preparations stained by the van Gieson method showed conclusively that the areas of necrobiosis were dispersed among the collagen bundles and at their expense. In the areas of infiltration the collagen was destroyed and had been replaced by the cells, but between the foci the collagen appeared to be practically normal.

Sections prepared by Weigert's method showed only fragments of elastic tissue throughout the entire corium, and they were completely lacking in the necrobiotic foci.

The results of microscopic examination in this case are in accord with those reported by Oppenheim, Urbach and Balbi.

In our case, from a superficial survey of the formaldehyde-fixed frozen sections, which were stained with sudan III and counterstained with hematoxylin solution one could readily observe that the heaviest sudanophilic foci coincided with the necrobiotic areas and that they showed a staining reaction which was definitely different from that of the neutral fat of the subcutaneous tissue. Whereas the latter appeared a brilliant orange-red, the lipoids in the necrobiotic masses assumed a dull brown. The lipid containing tissue was more dense in the center of these masses and gradually faded into the surrounding tissues.

Under higher magnification, both intracellular and extracellular lipid deposits were seen, although the extracellular accumulations were relatively more massive and consisted of much larger globules than those seen within the cells. The extracellular lipid was not only seen in the necrobiotic foci but was scattered diffusely throughout the corium as isolated fine droplets occurring between the connective tissue fibers. The intracellular lipid was contained in certain large fibroblastic cells, which seemed to be filled to overflowing, and numerous droplets of minute size that were stained with sudan could be seen about these cells. Some of the vessels in the necrobiotic foci, as well as in the infiltrated areas about the sweat glands, showed fatty substances in the vessel walls.

The collagen bundles in some of the sections appeared to be swollen and impregnated with tiny droplets of lipid, so that the entire bundle was stained a rusty brown.

**CASE 2—History**—M. H., a woman, aged 48, stated that she had diabetes mellitus since May 1932. The condition was discovered during a period of hospitalization for influenza. She was not treated until March 1933 when she became weak and sugar was discovered in the urine. At this time a physician outlined a diet and recommended the injection of 10 units of insulin twice daily. In November 1933 she injured the small toe of the right foot, while attempting to remove some dead skin. Soon afterward the toe became swollen and she was unable to wear a shoe. She attempted to reduce the swelling by means of a hot flaxseed poultice causing several bullae on the dorsum of the right foot. Neither the original injury on the toe nor the bullae healed during the following six weeks. The patient came to the University Hospital for advice.

She related at this time that her mother had died of diabetes and that her husband and one child were living and well.

**Examination**—At the time of admission Jan. 8, 1934, the patient was well developed and in good health except for the present complaint. The heart, lungs and other internal viscera were apparently normal.

On the dorsum of the right foot there were five superficial ulcers. The largest one was oval, measuring 3 by 6 cm, and was surrounded by a deep violet zone 2 cm in width due to hemorrhage beneath the surface. The other lesions were identical except for size. Two were situated at the level of the malleoli and two were at the base of the toes. All were about 1 to 2 cm in diameter and appeared as bullae from which

Fig 1 (case 1)—Lesion of three years duration in a girl aged 10 years

the tops had been removed. The right small toe showed an area of granulation tissue 2 mm in diameter on the lateral and medial surfaces. The left leg and foot were normal.

**Laboratory Data**—The urine at the time of admission showed a strongly positive reaction for sugar. The blood showed hemoglobin, 90 per cent leukocytes, 8300, polymorphonuclears, 71 per cent, lymphocytes, 25 per cent monocytes, 3 per cent, basophils, 1 per cent.

The Wassermann and Kline tests were negative. The fasting blood sugar was 176 mg per hundred cubic centimeters, and the fasting blood cholesterol was 181.5 mg per hundred cubic centimeters.

Röntgen examination of the right foot showed an osteomyelitis involving the outer portion of the first and terminal phalanges of the right small toe. There was also a sclerosis of some of the vessels of the right leg and foot.

**Progress**—After treatment for two weeks with antiseptic wet compresses the toe, as well as the ulcerations on the dorsum of the foot and on the toe, healed. At this time the lesions assumed the typical characteristics of necrobiosis lipoidica diabetorum. All were similar except in size which varied from 1 to 7.5 cm. Each lesion corresponded exactly to the site of previous ulceration. The largest which was situated near the external malleolus was somewhat irregular but roughly oval. It measured 5 by 7.5 cm and extended medially from the malleolus to a point about 2 cm to the right of the midline. There were two other lesions on the dorsal surface of the ankle at the level of a line drawn between the two malleoli. Both were oval and were 3 by 2 and 4 by 3 cm in size the long axes being longitudinal. The two other lesions were located near the base of the toes and were 1 and 2 cm in diameter.

All the lesions were waxy plaques, of firm consistency, and sharply demarcated from the surrounding normal skin. The color of the three largest lesions was dark purple, deepest in the center and gradually becoming lighter and somewhat yellow toward the periphery. The purple of the plaques was not uniform over the surface but interspersed by yellow foci, which were irregular in size and shape. The largest lesion was capped by a thin white scale. No telangiectatic vessels were observed.

The two smaller lesions at the base of the toes were appreciably lighter in color than the three lesions previously mentioned. They were similar in other features. The central portions were violet and appeared to be stippled with yellow. The surfaces were glistening and smooth and there were no scales.

A biopsy was taken from the largest lesion and the microscopic features were found to be essentially the same as those described in the first case.

Sections from both of our cases of necrobiosis were treated with the tinctorial agents as outlined in table 4. The staining reactions were identical with those reported by Urbach and Balbi, and we do not deem a detailed description necessary.

#### PATHOGENESIS

The pathogenesis of necrobiosis lipoidica diabetorum has been the cause of controversy and is still not entirely settled. Oppenheim was chiefly concerned with the fact that this cutaneous finding in diabetes was a clinical entity and on the grounds of his observations was inclined to consider as the basis for the disease a fatty degeneration of the connective tissues, such as Kreibich described in sailors' skin and cuts.

Fig 2 (case 2)—Lesion present three months in a woman aged 48

rhomboidalis nuchae. He emphasized the fact that the microscopic changes were entirely different from those of xanthoma diabetorum for there was a complete absence of xanthoma and giant cells.

In his publication and discussions before medical societies, Oppenheim maintained that the degeneration was brought about by circulating toxic substances which were an accompaniment of the diabetes and which

by their local action caused a colloidal-chemical change in the tissues. Although his histologic studies showed no amyloid, colloid, hyaline or mucinous degenerations, he deduced from his study of the sections stained by the van Gieson method that there was some specific change in the connective tissue. In sections stained with sudan III he found intracellular and extracellular lipid droplets.

Urbach considered the condition to be a necrobiosis of the connective tissue followed by an imbibition of lipoids. He stated, in objection to Oppenheim's views, that the lipid degeneration described by Kreibich about twenty years ago was in no way analogous to the process that occurred in necrobiosis lipoidica diabetorum. In the former instance the sudanophilia that Kreibich found was limited exclusively to the swollen, fragmented elastic fibers, while in the latter condition the chief changes appeared in the connective tissue, with the elastic fibers for the most part completely lacking in the necrobiotic areas.

As a further objection to the theory of local degeneration as an explanation of the pathogenesis, Urbach

After a fair consideration of both views and an excellent, painstaking, microchemical investigation, Balbi felt that the conception of Urbach was correct. At first glance, because of the mild reaction of the tissues, he was undecided as to whether or not the process was one of necrobiosis and imbibition or one of degeneration. He believed that the nuclear alterations, the disappearance of cells, the restriction of the vessel lumens, due to thrombosis, and the homogenization of the connective tissue was indicative of necrobiosis, while the negative reactions for amyloid, colloid hyalin and mucin, which Oppenheim obtained, were against degeneration. For the same reasons that Urbach had given he concurred in the view that degeneration, in the sense that Kreibich uses the term in sailors' skin, could not be applied to this disease. Balbi found that most of the lipid deposits were extracellular, and the few cells containing sudanophilic inclusions were histiocytic fibrocytes of normal appearance. They were not degenerated, as would be expected if the process was one of lipid degeneration. He thought that the arrangement of the droplets in clusters and striae did not carry the significance that Urbach attributed to it.

In some sections, however, he observed masses of lipid within thrombosed vessels and rich perivascular deposits around others, strongly indicating that the lipid was blood borne and deposited in greatest quantities in the immediate vicinity of the vessels, gradually invading areas farther distant. In many places he saw degeneration of the vessel wall caused, he believed, by toxic materials circulating in the blood other than the lipid.

He thought that the clinical facts coincided well with the histologic observations. The surface telangiectasia was explained as a compensatory phenomenon secondary to disturbances in the deeper vessels. The brown discoloration of the lesions was due to iron pigment deposited in the upper part of the corium, and the yellow tint was given by the lipoids present in the lesions. He felt that the prolonged course of the disease was due to the torpidity of reaction that characterizes diabetic tissues. In cases such as Balbi's, in which the necrobiosis is more intense the foci may liquefy and cause ulcerating lesions. In the ordinary, milder cases the peripheral circulation maintains the integrity of the epidermis.

#### COMMENT

After a critical evaluation of the literature and a prolonged study of our cases we attempted to arrive at a conclusion regarding this condition. We felt that an attempt should be made to align a new dermatosis that could be attributed directly to the diabetic process with the two best known cutaneous complications of diabetes. These are xanthoma and gangrene. Furthermore, we were convinced that the absence of xanthoma and giant cells definitely excluded the possibility that the dermatosis is an atypical form of xanthoma diabetorum.

There is no question but that trauma played an important role in the development of the lesions in our two patients. Since our attention has been attracted to necrobiosis lipoidica diabetorum, we have minutely examined the skin especially of the lower extremities, of every patient in the diabetic service who showed any cutaneous abnormality. We have seen lesions which in their evolution passed through a phase that

Fig. 3—A necrobiotic focus surrounding a blood vessel found at biopsy in case 1.

cited the belief, which is prevalent among pathologists at the present time (von Gierke in Aschoff), that it is improbable but not indisputable that fat can originate from cell protein. The accepted view is that the lipid in such degenerations comes from the blood or lymph streams and not from the cells themselves.

In support of his own ideas regarding the pathogenesis, Urbach claims that the arrangement of the lipid droplets in chains and clusters makes it appear probable that they come from the blood stream, and that it is the current belief that all necrotic tissue masses of the type found in necrobiosis lipoidica diabetorum attract substances circulating in the blood. Such a state exists in diabetes, as is illustrated by the finding of hyperlipemia. Hence the necrotic masses take up the circulating fatty substances.

Urbach supposed that certain toxins due to diabetes caused a severe disturbance in the vessels of the corium leading to necrobiosis as evidenced by loss of cells and nuclei homogenization of the connective tissue and the deposition of calcium salts. These primarily necrobiotic tissues then imbibed lipid substances, which are so often in the blood of diabetic subjects.

was identical in appearance with the lesions in necrobiosis lipoidica diabetorum. In some of these patients the process advanced to a frank gangrene, while in others the lesions disappeared without a trace. We concluded, therefore, that the disease was more closely related to gangrene than to any other integumentary process in diabetes.

We familiarized ourselves with the opinions of various authorities regarding the pathogenesis of diabetic gangrene and were surprised to learn that in spite of the vast literature on diabetes produced in the past decade there had been little study of gangrene.

We made biopsies at various distances from gangrenous areas in diabetic patients in an effort to ascertain whether or not the tissues adjacent to diabetic gangrene showed necrobiotic foci, and we felt that there was sufficient similarity to consider the processes closely related, the variation being mostly one of degree. We also cut sections from tissue surrounding gangrenous areas in patients who did not have diabetes. We especially searched for sudanophilic substances and found them in varying amounts. It was our opinion that in diabetic patients with a hyperlipemia the amount of fatty substance found in the necrotic areas was greater than in nondiabetic patients, although lipoids were present in both. We were convinced that necrobiosis lipoidica diabetorum was closely allied to gangrene, and that the degree of trauma, the anatomic location, and the severity of the underlying diabetes were the factors on which the course depended.

The composition of the lipoids found in this process is undoubtedly of interest to biologic chemists. However, we believe that the clinical lesions could be identical regardless of the predominating type of lipid found and, furthermore, that the imbibition of lipid was preceded by a primary vascular disturbance. The size and location of the vessels involved must govern the extent of the tissues injured, and this in turn influences the amount of fat deposited. Other factors, such as the relative amounts of the various lipoids in the blood, must play a role in determining the identity of the substances that are present in the tissues.

#### CONCLUSIONS

1 Necrobiosis lipoidica diabetorum is a definite entity that is more distinctive clinically than pathologically.

2 The process is more closely allied to diabetic gangrene than to diabetic xanthoma.

**Disturbances of Nutrition**—Although pernicious anemia, pellagra, sprue, possibly the idiopathic steatorrhea or celiac disease and even hunger edema possess individual characteristics that give them the distinction of clinical and etiological entities, there are considerable numbers of patients who suffer from profound disturbances of nutrition in which the clinical picture is not so clear cut, and in which, in addition to malnutrition, several features peculiar to two or more of the above diseases may be combined in a most confusing manner. The variations in symptoms and signs may be numerous. There may be great loss of weight, anemia either of the microcytic or macrocytic type, persistent diarrhea, glossitis, steatorrhea, skin eruptions, abnormalities in mineral metabolism and alterations in the exchange of fluids so that in some patients there is dehydration of the subcutaneous tissues while in others such extensive edema that it becomes one of the predominant features of the illness—Longcope W T. The Importance of Disturbances in Nutrition in Edematous States, *Voc England J Med* 210 1243 (June 14) 1934.

## ELECTROSURGICAL OBLITERATION OF THE GALLBLADDER

(SEVENTY-FIVE CONSECUTIVE, UNSELECTED, CASES WITHOUT MORTALITY)

MAX THOREK M D

CHICAGO

Although standard methods of cholecystectomy yield in competent hands an immediate operative mortality, in selected uncomplicated cases, of 1 or 2 per cent, no such happy results are recorded in hands not especially trained, particularly in complicated cases and in patients over 40 years of age. The global mortality in surgery of the gallbladder in complicated cases remains too high. The statistics of Enderlen and Hotz,<sup>1</sup> based on 12 144 cases of biliary tract disease treated surgically by vari-

Fig 1—Effects of forced carbonization on wall of inflamed gallbladder: (1) eschar; (2) Rokitansky Aschoff sinus in transverse section; (3) muscularis; (4) serosa. An excellent state of preservation characterizes the layers of gallbladder past the mucosa. Slightly reduced from a photomicrograph with a magnification of 85 diameters.

ous competent operators, gave an immediate operative (global) mortality of 9.28 per cent.

Verbruycke,<sup>2</sup> quoting Lyons, states that in a review of a series of his cases in which operation was performed by first class surgeons the immediate mortality was 10 per cent, and there were serious hospital complications in 33 per cent. Table 1 is of interest in this connection. The greater mortality in males as compared with females is striking.

Scalpel surgery of the gallbladder, therefore, must not be judged by the brilliant results of a few exceptional operators but by the general results of the average surgeon (who often does not report his results). These may in many instances give immediate mortalities of 20 or 30 per cent or even higher.

CAUSES OF DEATH AND COMPLICATIONS

The most frequent causes of death and complications following scalpel surgery of the biliary tract are peritonitis, shock, hemorrhage, pulmonary embolus, pneumonia and cholera. The first four are by far the most

common and seem to be more or less inseparable from any form of scalpel surgery. In most instances they are directly traceable to biliary seepage, particularly from the bed of the gallbladder, which contains not only

bile capillaries (often dilated) but also bile ducts of considerable caliber in from 15 to 25 per cent of individuals. These are injured during the course of cholecystectomy, and bile seepage results. Furthermore, it is not always possible to cover the denuded surface of the liver bed with peritoneum in a classic cholecystectomy. Bile, sterile or not, has been proved to act as a true chemical poison in the peritoneal cavity. Drainage invites bile seepage. Bakes<sup>3</sup> observed bile issuing from the wound 230 times in 346 cases of simple cholecystectomy. He and many other surgeons were impressed by the postoperative appearance of bile in the dressings "in nearly all the cases."

DANGERS OF DRAINAGE IN CHOLECYSTECTOMY

The dangers and evils of drainage are well known. Briefly, they are bile seepage (biliary peritonitis), hemorrhage (arrosion of vessels), cardiac embarrassment (particularly in the aged), acute dilatation of the stomach, pneumonia (usually right lobar), fistulas, hernias, evisceration, stenosing sequelae, and the like.

The profession is still too much under the thrall of Kehr's famous dictum that "proper drainage is half a successful gallbladder operation." Nevertheless it appears in the light of recent reports that drainage might also be considered as half an unsuccessful operation. Davis<sup>4</sup> also called attention to the evils of drainage. There seems to be no doubt that, *ceteris paribus*, a gallbladder operation without drainage has a better chance of success than if drained. Many of the dangers are eliminated by omitting drains. Theoretically, a dry field and a tightly closed abdomen are ideal, but a scalpel cholecystectomy with completely satisfactory peritonization cannot always be accomplished.

Fig 3—Mrs A M Chronic cholecystitis eight months after (mucoclasia) electrocarbonization of the mucosa. Note remnants of Rokitsky Aschoff sinuses and diffuse round cell infiltration. Below in center of field an aggregation of polymorphonuclear leukocytes. Reduced from a photomicrograph with a magnification of 105 diameters. Persistence of symptoms. Relieved by total obliteration of gallbladder wall by electrocoagulation.

In certain conditions drainage is a necessity, namely, in obstruction in the common bile duct, icterus, progres-

sive septic cholangitides, inability to peritonize the cystic duct and gallbladder bed, and the like

#### SOURCES OF GALLBLADDER INFECTION

Patey and Whitby summarized their observations as follows 1 Experimentally, the cystic artery is the easiest route by which organisms can reach the gallbladder 2 The liver is not an efficient bacterial filter Bacterial emboli may therefore reach the gallbladder

Fig 4—Mrs M L Chronic cholecystitis nine months after electrocarbonization of mucous membrane of gallbladder (mucoclasia). No relief of symptoms. Regeneration of mucous membrane and persistence of inflammation (round cell infiltration and the like). Reduced from a photomicrograph with a magnification of 220 diameters. Relieved by electrocoagulation of entire gallbladder wall

as easily from a portal focus as from a systemic one 3 There is evidence that lymphatic spread from the liver to the gallbladder is a probable route 4 The possibility of infection of the gallbladder by bile descending from the liver cannot be dismissed. Ascending infection from the duodenum is, however, probably extremely rare. Evarts Graham,<sup>5</sup> commenting on this, states that Patey and Whitby are wrong in their assumption that there is no evidence of a lymph flow from the liver to the gallbladder. Sudler, in Mall's laboratory at Johns Hopkins, more than thirty years ago demonstrated this flow in the pig. It is true, however, that in 1927 Winkenwerder, also of Johns Hopkins, was unable to find such a flow experimentally in the cat.

The studies of Andrews and Hrdina<sup>6</sup> have shown that infection of the gallbladder occurs by direct extension from the liver. They have produced hepatogenous cholecystitis by creating biliary stasis after ligating the cystic duct in dogs.

It is conceded that the gallbladder is only a part sharing in an infectious process in the biliary apparatus. Clinical results following its removal, however, seem to indicate that it often is the main focus, and, while the liver is usually amply fortified to cope with invading micro-organisms, the gallbladder seems to be a *locus minoris resistentiae*, which succumbs to the destructive influence of pathogenic micro-organisms. The best damage of the biliary system is that which follows continuously after cholecystectomy through the common duct into the duodenum.

#### HOW CAN THE EVILS OF DRAINAGE BE REMEDIED?

The logical answer seems to be (a) by omitting drains if possible, (b) by so protecting the gallbladder

bed that no bile leakage results, and (c) by eliminating the infected gallbladder. All these can be effectually accomplished by a procedure to be described.

The raw surface resulting from a dissection of the gallbladder from its bed is the *bête noire* in cholecystectomy. Injury to the gallbladder bed and the resultant division of bile passages nearly always result in biliary seepage, and not all gallbladder beds can be covered with peritoneum after classic cholecystectomy. Bile seepage will not result from the divided cystic duct when it is thoroughly peritonized with serosa of the hepato-duodenal ligament. Such being the case, elimination of seepage from the gallbladder bed seems to be the keynote of the problem. I have shown<sup>7</sup> that this can be effected (1) by electrocoagulation of the entire thickness of the gallbladder wall, and even the liver bed. Such procedure results in an occlusion (by coalescence) of the capillaries and bile ducts and by formation of a dry, sterile layer of inert tissue, (2) by covering the electrocoagulated area with the ligamentum falciforme hepatis for further protection, and (3) by omitting drainage.

#### EVOLUTION OF THE METHOD

Pribram<sup>8</sup> states that surgeons preceding him practiced extensive partial cauterization of the mucous membrane of the gallbladder with the Paquelin burner for purposes of avoiding fistulas. He extended such "charring" or "burning" to larger areas of the gallbladder mucosa and called this procedure mucoclasia. As recently as 1933<sup>9</sup> he still speaks of "carbonization of the mucosa of the gallbladder." I have shown elsewhere<sup>7</sup> that such cauterization of the mucous membrane of the gallbladder (mucoclasia) is insufficient to eliminate the gallbladder and eradicate disease. A charred

ing with it the potential danger of partial or total detachment, which may result in hemorrhage, thrombosis and possible embolism. Albertin<sup>10</sup> has shown that Pribram lost nine patients in a series of 310 cases in which mucoclasia was employed. Coupled with this drawback there is still another, more important, factor, which is that the incomplete destruction of the gallbladder wall by carbonization defeats its purpose by

Fig 6—*a* aspiration of gallbladder contents *b* ligation and division of cystic duct

permitting micro-organisms to remain dormant in the Rokitsky-Aschoff sinuses. Carbonization is a superficial process. Electrocoagulation, on the other hand, permits destruction of tissue to any depth desired, simultaneously sealing lymphatics, blood vessels and biliary canaliculi (figs 1 and 2). It leaves a dry, sterile impervious surface tending to agglutination with serous surfaces. To be successful, destruction of the gallbladder wall must be thorough and extend through the entire thickness of the wall and as far into the tissues of the gallbladder bed as conditions warrant.

Graham<sup>11</sup> emphasizes that "very often the dependent layers of the gallbladder, especially the subserous layer next to the peritoneum, show the most severe inflammatory changes while the epithelium may look intact in the most severe grades of inflammation." The studies of Rosenow,<sup>12</sup> Brown,<sup>13</sup> Illingworth,<sup>14</sup> Wilkie<sup>15</sup> and others substantiate this view.

Figures 3 and 4 are from two of a series of cases in which only destruction of the mucous membrane of

the gallbladder was done. They prove the inefficacy of destruction of the mucosa in gallbladder disease. In both instances, mucoclasia was done without any clinical improvement. On the contrary, the condition of the patients became aggravated. Attempts at regeneration of the mucous membrane with persistence of inflammation in the deeper layers of the gallbladder wall and liver bed are the striking microscopic changes. Relaparotomy and cholecystelectrocoagulectomy gave relief in both cases. These cases are cited as examples of similar experiences in the rest of a series in which only the mucous membrane was attacked. Failures with subserous enucleation of the gallbladder and with classic cholecystectomy led to the evolution of total electrocoagulation of the gallbladder wall and the liver bed, with superimposition of the falciform ligament and the omission of drainage.

#### RATIONALE OF THE PROCEDURE

In patients seeking relief from symptoms of gallbladder disease, the surgeon often finds the gallbladder macroscopically normal at operation, but cholecystectomy frequently relieves these patients of their complaints. Histologically such gallbladders often contain diverticula, foci of infection, intramural abscesses and intramural calculi. The mucosal infoldings (Rokitansky-Aschoff sinuses) described by Luschka in 1863 and later by Aschoff in 1905 frequently harbor cholesterol concretions (stones), islands of round cells surrounding these diverticular outpouchings are commonly observed. Schmiedheiny<sup>16</sup> concludes that "in all forms of cholecystitis the so-called liver bed is almost always affected." Here the pathologic processes transgress

Fig 7—Diathermy scissors for ablation of gallbladder wall and simultaneous hemostasis

the tunica fibrosa and encroach on the subserosa and serosa, and frequently invade the contiguous liver parenchyma, particularly in the more serious forms of gallbladder disease.

Electrocoagulation provides an efficient method of eradicating such foci. As shown by Zschau<sup>17</sup> the electrocoagulating current does not cause thrombosis in the

blood capillaries and smaller vessels. The possibility of embolus is thus greatly minimized. When a coagulated area is peritonized there results a solid, more or less homogeneous, dehydrated, hyalinized mass that acts as a sterile tampon in the bed of the gallbladder, and the tissues of such electrocoagulated areas tend to prompt healing by encapsulation and final absorption. Kuntzen and Vogel have shown that electrocoagulated areas of

thrombus formation. Secondary hemorrhage does not occur because of the pressure exerted by the sequestered coagulated mass against the connective tissue capsule.

#### OPERATIVE TECHNIC

The operative technic has been fully described elsewhere.<sup>18</sup> Briefly, it is as follows: General or spinal anesthesia (tropicaine hydrochloride, 10 per cent), ample exposure, mobilization of the falciform ligament, aspiration of the gallbladder contents and exploration

TABLE 2—Analysis of Seventy-Five Cases

Total number of cases	75
Males	2
Females	73
Age of patients—youngest	29 years
oldest	69 years
Average high temperature	100 F
Average number of days in hospital	14.5
Pathologic conditions found at operation	Acute and chronic cholecystitis, cholelithiasis, hydrops vesicae felleae, empyema of the gallbladder, acute hemorrhagic cholecystitis, hepatitis, adhesions, pancreatitis (chronic)
Postoperative complications	None except in one case in which a cholecystectomy was done for gangrenous cholecystitis and cholelithiasis. The sutures were removed on the eleventh day. The wound healed by first intention. On the tenth postoperative day symptoms of bilateral pleurisy with effusion were noted which cleared up. The patient left the hospital on the twenty-seventh day in good condition.
Mortality	None

Fig. 8—Redundant portion of gallbladder removed. Remaining portion of gallbladder wall attached to gallbladder bed electrocoagulated.

the liver in guinea-pigs and dogs tend to prompt adhesions between the omentum, the covering of the intestine, or any contiguous serosal surface. Adhesions thus formed were dense at the height of the reparative process but later tended to regress, and after some months "only a few fine strands connected the coagulated area with the omentum." I had occasion to substantiate these observations in some of my experimental studies (fig. 5) on the dog and *Macacus rhesus*.

Electrocoagulation produces entirely different effects than thermocauterization and electrocauterization. Electrocoagulated areas on the surface tend to extrusion, while in the abdomen there result agglutination, encapsulation and absorption.

Electrocoagulation of the liver results in definite tissue reactions. A zone of necrosis is observed at the point of contact with the electrode. This is limited by a line of demarcation consisting of leukocytes. Beyond this, another, less extensive, zone of necrobiotic tissue is observed, which is again limited by a zone of leukocytes and wandering cells. From this layer encapsulation proceeds, and from within the protective connective tissue capsule absorption of the coagulated tissue takes place. Hemostasis as a result of diathermy does not take place by thrombosis but by collapse and fusion of the walls of the vessels.<sup>18</sup> According to Aschoff, coagulation thrombosis is in sharp contradistinction to true

of the biliary passages, double ligation and division of the cystic duct and artery (fig. 6), removal of the redundant part of the gallbladder wall by special dia-

Fig. 9—*a* electrocoagulated zone approximated with sutures. *b* pedicle flap of ligamentum falciforme hepatis ready to be sutured over suture line covering electrocoagulated zone.

therm scissors, during which the branches of the cystic artery coursing in the gallbladder wall are simultaneously coagulated (fig. 7). Only that portion of the wall of the gallbladder is permitted to remain which is attached to its bed. This is slowly electrocoagulated to the depth required (fig. 8).<sup>19</sup> Approximation of the

edges of the coagulated segment of gallbladder with catgut sutures. The falciform ligament is attached to the coagulated area by sutures previously left long (fig 9), no drains.

A series of seventy-five patients were operated on by this method, without a death. An analysis of this series is given in table 2.

#### SUMMARY

Failures and fatalities in classic cholecystectomy are frequently due to bile leakage, as a result of an inability to obliterate and cover the gallbladder bed, which contains bile capillaries and often larger bile ducts, in from 15 to 25 per cent of cases. Drains invite bile seepage. A method is described which effectually seals these openings by electrocoagulation. A sterile, hyaline, dry protective layer is substituted for a raw, unprotected surface. The falciform ligament is superimposed over this area. Drainage is entirely omitted. A series of seventy-five consecutive, unselected cases were thus treated without a fatality.

### SUPRAPUBIC PROSTATECTOMY WITH IMMEDIATE CLOSURE OF THE BLADDER

#### IMPROVED METHOD OF POSTOPERATIVE DRAINAGE

H. H. HAYNES, M.D.

CLARKSBURG, W. VA.

The advantages of immediate closure of the bladder are apparent to every one familiar with prostatic surgery, provided the hazards of faulty drainage and complications are not increased.

My experience with eight cases of primary closure, with postoperative drainage by a return flow catheter, would indicate that by this method drainage can be improved and the occurrence of complications materially reduced. This catheter is an original modification of Dr. Chetwood's suprapubic drainage tube designed for retrograde introduction into the urethra.

#### OPERATIVE PROCEDURE

The usual suprapubic incision is made. When the bladder is opened, suction is used to remove the contents of the distended bladder and thereby avoid unnecessary soiling of the wound. After enucleation of the prostate, complete hemostasis is obtained and the prostatic fossa is obliterated with No. 0 plain catgut. An ordinary catheter used for irrigating and distending the bladder is left in the urethra during the operation. Before the fossa is obliterated, the end of the small intake tube (fig 1 B) of the special drainage catheter is sutured with strong silk or linen to the tip of the catheter introduced before operation (fig 2 A). The urethral catheter is now withdrawn by an assistant and the special catheter, well lubricated, readily follows through the urethra.

When the distal end of the drainage catheter is withdrawn the assistant removes the intake tube from the main catheter (fig 1 A) through the small oval opening (fig 1 D). The button flap (fig 1 C) is adjusted over the intake tube and fastened in position to prevent leakage of the return flow. The intake tube is then attached

to the irrigating apparatus and the return flow tube connected to carry the return flow into a suitable receptacle. The irrigation is now turned on to demonstrate that the drainage catheter is functioning properly.

After obliteration of the prostatic fossa and complete hemostasis, the Pezzer tip of the drainage catheter is drawn snugly into position (figs 3 and 2 B).

The usual suture to obliterate the space of Retzius is now placed but not tied. After this the bladder incision is closed completely with two rows of No. 0 chromic catgut. The first row of sutures should include all the muscularis but not the mucosa and is a continuous lock suture. This row is completely buried by a continuous Cushing right angle suture.

The suture, previously placed to obliterate the space of Retzius, is then tied. This suture is of great importance both in obliterating the space of Retzius and in preventing tension on the bladder incision.

The abdominal wound is closed in the usual manner except that several loops of catgut extending down to the bladder are placed in the lower angle of the incision for drainage of the prevesical space; these are removed on the third day.

Before the patient is removed from the operating table, the catheter is anchored to the penis in the usual manner.

#### AFTER-TREATMENT

Continuous irrigation, by the drop method, is started before the bladder is completely closed and continued twenty-four hours. On the second day irrigation is done every four hours, and after the second day irrigations morning and evening are usually sufficient. Boric acid solution has been used in these cases. Heat is an important factor in the irrigation but care must be used

Fig. 1—Return flow irrigating catheter designed for retrograde introduction. Upper catheter adjusted for introduction, lower catheter adjusted for irrigation and drainage. A, main catheter containing intake tube and space for return flow. B, intake tube. C, button flap to prevent leakage of return flow. D, oval opening for bringing intake tube out of main catheter. E, Pezzer tip (drainage catheters made by Clay Adams Company, 25 East Twenty-Sixth Street, New York City).

to avoid burning the patient. Local treatment to the bladder can be used easily through this catheter.

The drainage catheters have been removed from the seventh to the tenth days and so far as I can see the patients from whom catheters were removed on the seventh day have done as well as those from whom catheters were removed later.

To remove the drainage catheter I start with a steadily increasing pull until the patient shows evidence of discomfort and then complete the withdrawal by a

quick harder pull. None of these patients have had difficulty in voiding following removal of the drainage catheter.

#### REPORT OF CASES

CASE 1—J L J, aged 61, was admitted, Oct 17, 1932, and discharged, November 2. Operation was performed October 19, the catheter was removed October 29, and the patient was out of bed October 30. The pathologic diagnosis was hypertrophied prostate.

CASE 2—T C, aged 81, was admitted, Jan 22, 1933, and discharged, February 19. Operation was performed January

Fig 2—Schematic drawing showing A method of retrograde introduction of drainage catheter B Pezzet tip in position

31 the catheter was removed February 9, and the patient was out of bed February 13. The pathologic diagnosis was carcinoma of the prostate.

CASE 3—P F C, aged 83, was admitted, May 17, 1933, and discharged, June 3. Operation was performed May 20, the catheter was removed May 29, and the patient was out of bed May 31. The pathologic diagnosis was tuberculosis of the prostate.

CASE 4—W F L, aged 77, was admitted, June 20, 1933, and discharged, July 13. Operation was performed June 28, the catheter was removed July 6, and the patient was out of bed July 7. The pathologic diagnosis was benign hypertrophy.

CASE 5—E H C, aged 76, was admitted, Sept 22, 1933, and discharged, October 9. Operation was performed September 28, the catheter was removed October 5, and the patient was out of bed October 7. The pathologic diagnosis was benign hypertrophy.

CASE 6—G B, aged 51, was admitted Nov 20, 1933, and discharged, December 14. Operation was performed December 4, the catheter was removed December 11, and the patient was out of bed December 12. The pathologic diagnosis was adenoma of the prostate.

CASE 7—J E C, aged 59, was admitted, Nov 28, 1933, and discharged, December 29. Operation was performed December 11, the catheter was removed December 20, and the patient was out of bed December 23. The pathologic diagnosis was adenomatous hypertrophy.

CASE 8—F U K, aged 65, was admitted, Jan 2, 1934, and discharged, January 16. Operation was performed January 6, the catheter was removed January 13, and the patient was out of bed January 14. The pathologic diagnosis was benign hypertrophy.

This is not a series of selected cases. They have been taken in order as they came in a general surgical practice. Case 2 was adenocarcinoma in a man, aged 81, and was an ambulance case. Case 7, in addition to prostatic obstruction, presented toxic goiter, auricular fibrillation (shown by electrocardiography) and cardiac insufficiency with passive congestion. Except for the myocardial condition, the patient could have been discharged on the tenth or eleventh day.

Vasectomy was not performed in any of these cases and epididymitis or other complications did not occur. There was no bladder leakage in any of these cases and all suprapubic wounds were completely healed when the patients were discharged from the hospital.

The patients comprising this series have been communicated with in the last ten days and none of them have had any complications since leaving the hospital, all reported satisfactory results. The report from patient 2 (adenocarcinoma) through his family physician was that he had had no trouble with urination since leaving the hospital.

The average postoperative hospital stay of these patients was fourteen days. Two were discharged on the tenth postoperative day. The average postoperative time for removal of the catheter and for establishing natural micturition was eight and one-fourth days.

Only one of these patients complained of severe postoperative pain, and an investigation showed an obstruction of the return flow tube due to a faulty connection. This pain was immediately relieved when the return flow was put in order. Three of these patients voluntarily stated that at no time following their operation were they as uncomfortable as they had been before.

Evaluation of kidney function, intelligent preoperative care, hemostasis, obliteration of prostatic fossa and careful bladder closure are essential to success.

Fig 3—Interior of bladder with fossae obliterated and Pezzet tip in position

All these patients were anesthetized with tribromethanol, supplemented with gas-oxygen or ether when necessary.

#### ADVANTAGES OF THIS METHOD OF DRAINAGE

First, continuous or intermittent return flow irrigation with any desired solution.

- Second, better drainage
  - Third, shorter hospitalization
  - Fourth, no suture anchorage in the bladder
  - Fifth, assistance from Pezzet tip in obliterating prostatic fossa
  - Sixth, better anatomic and functional results
- 211 Goff Building

## SKIN SENSITIVENESS TO TUBERCULIN IN PRIMARY TUBERCULOSIS

IS ITS DEGREE IN CHILDREN RELATED TO THE  
EXTENT OF DEMONSTRABLE INTRATHORACIC  
PATHOLOGIC CHANGES PRESENT?

CHESTER A. STEWART, MD

MINNEAPOLIS

The degrees of skin sensitiveness to tuberculin manifested by infected children are found to vary widely when Mantoux or Pirquet tests are applied. It is also a matter of common experience to observe that, on the basis of physical changes and evidences indicative of disease or illness, individuals who are highly allergic to tuberculin protein cannot be differentiated, as a rule, from other infected children who have small or mild skin reactions. Despite the absence in general of detectable differences in the health status of children paralleling the varied degrees of allergy present, and regardless of a lack of knowledge as to why the intensity of tissue responses to tuberculin is markedly dissimilar in different individuals, it is often difficult to avoid entertaining suspicions that children with exceptionally large and severe Mantoux reactions either harbor more tuberculous pathologic changes or have more active and potentially more serious lesions than do other patients whose responses to tuberculin are smaller. My object in this paper is to present the results of studies directed particularly toward investigating the question: Is the degree of skin sensitiveness to tuberculin present in children with the first infection type of tuberculosis related to the extent or character of the primary intrathoracic pathologic condition that can be demonstrated during life by roentgen examinations?

Observations on 188 Lymanhurst School children ranging from 8 to 17½ years of age provided the data on which this report is based. Each child selected for study was sensitive to tuberculin, and as a result of repeated roentgenologic and clinical investigations the group was known to include six children with parenchymal infiltrations that later resolved, to leave calcifications, fibrosis or no traces, 132 children with definite, conspicuous and characteristic calcified hilar glands or Ghon tubercles or both, twenty-one with negative chest plates, twenty-one with slight, questionable or inconclusive calcifications in hilar glands, and eight children with pleural thickenings. Roentgenograms were taken of the abdominal and cervical regions in only a few instances. Previous experience has indicated that the occurrence of demonstrable pathologic changes in these regions is rather infrequent in the children who come to Lymanhurst for examination; thus it seems that the incidence of lesions in these areas susceptible of being visualized roentgenographically probably is rather low in the cases selected for this investigation.

From the standpoint of general health, nutrition and freedom from manifestations of illness, the group studied was comprised of children who collectively were indistinguishable from normal uninfected school children. The differentiation of the former from the latter depended essentially on the results obtained by Mantoux tests and roentgen examinations. The group selected for special study presumably is fairly representative of the infected portion of the general child population except that in the Lymanhurst series the incidence of cases showing lesions demonstrable during life is rather high. No child was used in this investigation who had any form of demonstrable tuberculosis of the reinfection type. The deductions drawn from the observation made apply solely, therefore, to allergy in tuberculosis of the first infection type diagnosed as such after repeated roentgenologic and clinical examinations, and after months of observation.

The data recorded in tables 1 and 2 are based on a total of 1,864 surface area determinations (the area by-weight method being used<sup>1</sup>) made on 466 Mantoux reactions to 0.1 mg. of old tuberculin (Saranac Lake product). In compiling the data for the 188 cases studied, averages were computed for five groups of children classified separately according to their roentgen examinations (tables 1 and 2). For each child the maximum size found for the reaction when measurements were taken at the end of four successive intervals of twenty-four hours each was accepted as indicative of that individual's degree of skin sensitiveness to tuberculin, and these maximum measurements provided the basis for computing the values that appear in each table under the heading "average maximum reaction area."

Since the number of separate tests applied to different cases ranged from one to five, it was deemed advisable to calculate these averages according to two methods. In table 1 the mean maximum area of all the tests performed on each child was determined, and from these several individual means group averages were computed. In table 2, therefore, each child's degree of skin sensitiveness to tuberculin, as expressed in the maximum area to which the reaction grew, contributed to the average as a single observation regardless of whether one or several tests were performed on the individual. This procedure avoids permitting the data from one patient on whom several tests were applied from unduly influencing the average. The average maximum size of the reactions listed in column six of table 2 represents the means for all the tests applied. In this table, therefore, the extent to which the readings on one case influenced the average was dependent not only on the degree of allergy present but also on the number of separate tests performed on that individual. Since circumstances dependent on chance rather than selection based on sensitiveness to tuberculin determined the number of Mantoux tests applied to each child, it seems probable that means computed for the total number of tests performed represent with fair accuracy the average degree of skin sensitiveness present in the group, provided it includes a fairly large number of cases.

The average maximum size of the Mantoux reactions (37.2 sq. cm. in group A, table 1) in six children with primary pulmonary tuberculosis in the acute inflammatory or pneumonic stage exceeded that (33.2

From the Department of Pediatrics, University of Minnesota Medical School and Lymanhurst School for Tuberculous Children.

1. Stewart, C. A. Cutaneous Reaction to Tuberculin in Primary Pulmonary Tuberculosis. *Am. J. Dis. Child.* 45: 1229 (June) 1933. *Am. Rev. Tuberc.* 28: 844 (Dec.) 1933.

sq cm in group B, table 1) for 132 cases with primary pulmonary tuberculosis in the older, more latent, calcified stage by 40 sq cm. On computing the standard error for this difference a value of 0.58 is obtained, which signifies that fifty-six chances per hundred exist for this difference to arise by sampling or by chance. A similar analysis of the averages based on the total number of observations made on these two groups of children (groups A and B, table 2) reveals that twenty-two chances per hundred exist for the difference of

during the first few years that postdate the primary infection. Apparently, therefore, in infected children with demonstrable lesions considered as typical of tuberculosis of first infection, no definite and proved relationship exists between the average degree of skin sensitiveness to tuberculin and the character (freshness or latency) of the demonstrable primary tuberculous intrathoracic lesions present.

On comparing the average maximum reaction area of 33.6 sq cm for the 138 children with demonstrable

7.1 sq cm between the mean maximum reaction areas for the two series of cases to arise by sampling. Regardless of how the data are analyzed, therefore, they fail to show any difference of proved significance between the degree of skin sensitiveness to tuberculin in children with acute fresh pneumonic lesions of primary pulmonary tuberculosis as compared with that present in other children with first infection types of lesions in older, more latent calcified stages. This observation suggests that, shortly following the initial entry of tubercle bacilli into the body and before the acute lesions resolve, allergy reaches an average level, which is sustained with little or no significant change

lesions (groups A and B, table 1) with the mean of 31.3 sq cm for the fifty cases with negative chest films or with small or inconclusive lesions (groups C, D and E), the former are seen to have the larger average reaction area by 2.3 sq cm. Statistical analysis of these data reveals that forty-three chances per hundred exist for this difference (2.3 sq cm) to arise by chance. The difference, therefore, is not significant. A similar analysis of the averages derived from the total number of observations made in these two groups of cases (table 2) likewise failed to show any significant difference ( $\pm P = 14$ ) between the mean level of allergy in one series of children as compared with that present in

the other. When the group of fifty cases is subdivided into its component series of cases, the average degree of skin sensitiveness for children with negative chest films and also for children with questionable or inconclusive intrathoracic lesions (groups C and D, tables 1 and 2) is not found to differ significantly from the mean value determined for the 138 cases with distinct demonstrable lesions. This also applies to the small group of eight children with pleural thickenings, provided the averages are based on the mean reaction area for each case as computed in table 1. When, however, the mean is based on all the readings taken (table 2), a rather low average degree of allergy is found in the group. This low value is seen on inspection of the individual data (not recorded in the table) to arise from the fact that five Mantoux tests on one child, who had a pleural thickening associated with a bronchiectasis and who was only slightly sensitive to tuberculin, influenced the average to a considerable degree. The low level of allergy for this group can hardly be interpreted as significant.

and conspicuous intrathoracic lesions considered typical and representative of primary tuberculosis as compared with other infected children with negative chest films or with indefinite and inconclusive lesions, cumulative frequency or ogive curves were constructed representing the situation as found in these two groups of roentgenologically dissimilar cases. The position of each child on his respective curve in figure 4 was determined by the average maximum area of the several tests applied to that individual. Each case, therefore, contributed a single point to the curve for the group to which he belonged. Inspection of the curves in figure 4 discloses that the pattern of the distribution of different degrees of skin sensitiveness to tuberculin among children with negative or inconclusive chest films is very similar to that for cases presenting definite and conspicuous demonstrable intrathoracic lesions interpreted as scars typical of tuberculosis of first infection. The conclusion seems justified, therefore, that, as expressed in terms of the area of Mantoux reactions to old tuberculin, the incidence of different degrees of allergy

Fig 1—Condition in M. Z. aged 12½ years. Average maximum area of five Mantoux reactions was 113 sq. cm. In 1923 at the age of 1 year bilateral consolidations were present in each upper lobe which later resolved to leave bilateral apical Ghon tubercles and calcified hilus glands together with an area of fibrosis extending laterally from the right hilus.

Fig 2—Condition in D. Z. aged 15 years. Average maximum area of two Mantoux reactions was 66 sq. cm. Roentgenogram shows no definite lesions characteristic of tuberculosis of first infection.

Fig 3—Condition in P. B. aged 13½ years. Average maximum area of four Mantoux reactions was 104 sq. cm. In 1922 at the age of 2 years a parenchymal infiltration was present in the left upper lung field which resolved to leave a large Ghon tubercle and calcified hilus glands.

In general, therefore, the study failed to disclose the presence of any difference of proved significance in the average degree of skin sensitiveness to tuberculin in children with negative or inconclusive chest plates as compared with that present in other children with definite demonstrable intrathoracic lesions considered to be characteristic and typical of primary pulmonary tuberculosis. Apparently the degree of allergy to tuberculin protein manifested by infected children is quite independent of the absence, presence, scarcity, abundance or character of the intrathoracic lesions of tuberculosis of first infection that can be demonstrated during life. The lack of correlation between the area of the Mantoux reactions and the roentgenologic observations is illustrated by the cases shown in figures 1, 2 and 3. The data in table 2 also show that the growth and decline of the areas of reaction for children with normal or inconclusive chest films and for other cases with positive plates are quite similar.

In order to analyze and to portray the manner in which different degrees of skin sensitiveness to old tuberculin are distributed among children with definite

introduced into groups of children by chance infections with tubercle bacilli which leave no definite traces or scars that can be identified with certainty during life is not essentially different from that induced in other groups of cases by infections that leave definite typical demonstrable primary tuberculous lesions.

#### CONCLUSIONS

1 The average degree of skin sensitiveness to old tuberculin present in a group of infected children with negative or inconclusive chest films was essentially equal to that present in groups of cases with definite and conspicuous demonstrable intrathoracic lesions in different stages of resolution and considered characteristic and typical of tuberculosis of first infection. The mean level of allergy to tuberculin protein produced in groups of children by chance infections is independent, therefore, of the absence, presence, scarcity, abundance, size or character of the primary tuberculous lesions demonstrable by roentgen examinations during life.

2 The distribution of different degrees of skin sensitiveness to old tuberculin in a group of infected

children consisting of cases with normal or inconclusive chest films was found not to differ essentially from that present in other cases with distinct demonstrable intrathoracic lesions deemed characteristic of tuberculosis of first infection. The curves that represent the general pattern of the distribution of different degrees of allergy to tuberculin found in each group of cases are very similar.

3 This study on living patients failed, therefore, to disclose evidence that justifies one in entertaining suspicions that children with large and intense Mantoux reactions harbor more extensive pathologic changes or

Fig 4—Cumulative frequency curves showing the distribution of different degrees of skin sensitiveness to 0.1 mg of old tuberculin in infected children with and without definite demonstrable intrathoracic lesions

have more active primary tuberculous lesions than do other children who are less sensitive to tuberculin.

4 Groups of children with primary tuberculosis exclusively, who are dissimilar roentgenologically, are alike as far as the average group skin sensitiveness to tuberculin is concerned. Apparently soon after tubercle bacilli make their initial entry into the body and before the primary tuberculous lesions have time to resolve, allergy reaches an average group level that is sustained with little or no definite change throughout the first few years that postdate the primary infection.

5 Changes in the size of Mantoux tests throughout the periods of increment and decline of the reactions in children with normal or inconclusive chest films roughly parallel similar changes manifested by skin reactions in other children with definite demonstrable intrathoracic lesions typical of tuberculosis of first infection.

**Diagnosis of Intracranial Aneurysm**—The diagnosis of intracranial aneurysm cannot be made with any degree of certainty until rupture occurs. Focal signs, if present before rupture takes place, are not different from those found in other localized disease processes within the cranium, notably cerebral tumor. Furthermore, Fearnside, Cushing and others have pointed out that cerebral aneurysms which do not rupture rarely give rise to symptoms. The uniform clinical picture produced by aneurysms arising from the anterior portion of the circle of Willis makes the diagnosis during life possible.—Garvey P. H. Aneurysms of the Circle of Willis, *Arch Ophthalm* 11 1032 (June) 1934

## Clinical Notes, Suggestions and New Instruments

### THE HEREDITY OF A CONGENITAL WHITE SPOTTING IN NEGROES

CLAUDE E. KEELER, Sc D BOSTON

Numerous isolated cases of congenitally piebald Negroes are recorded in the early literature. Little is known of the parents or progeny in these cases. The individuals described by Ptolemy, Apollonius, Gumilla, La Mothe, Blumenbach, Arthaud and Le Vallois, and the ones painted by Le Masurier and by Da Rocha were probably of the same type as those with which this paper is concerned, but several of these authors may have described the same individual. The more recent accounts of Piffard, Maas, Gould and Pyle, Baudouin, Levi, Frassetto, Hutchinson, and Simpson and Castle (all reviewed and with complete bibliography<sup>1</sup>) doubtless all refer to members of the family to be discussed here. In the several published pictures of members of this family, the clothing has interfered with a complete portrayal of the character.

Individual 4 in the pedigree chart shows normal pigmentation to be present on the head, back, hands and feet. There is, however, a white head blaze and a patch of white under the chin. The abdomen, sides, arms and legs are in general white but are speckled with small patches of normally pigmented skin. This type of pigment distribution is present in all piebald members of this family, although it may be stated that the one here presented bears somewhat more white than the average.

Fig 1—Appearance front and back of markings on individual 4

The construction of the pedigree chart of this family has been made possible by correspondence with individuals 1 and 2 and by personal interviews with 3, 4 and 6. In figure 2, squares represent males, circles represent females and diamonds represent sex unrecorded. The black symbols represent the piebald individuals.

The character is said to have first appeared in female 1. This woman who is said to be 86 years of age was born and

From the Howe Laboratory, Harvard Medical School.  
I. Pearson, Nettleship and Usher. A Monograph on Albinism in Man.  
Draper's Company Research Memoirs. Cambridge University Press.

still resides in Louisiana. She states that she was born of normal parents. If this is the case, the character must have arisen as a mutation in the germ plasma of one of her immediate parents. Of course, the possibility remains that she might have had a piebald white father, the extent of whose white markings was not generally known owing to the normal color of his skin.

Isolated members of this family, and occasionally several members together, have traveled with circuses and freak shows in Europe and America ever since 1896, and individuals 3, 4

were cut off as close as practicable, and the dermatitis was treated with soothing dressings. It required about four weeks for the eruption to heal, and two months passed before she was able to resume her work.

The patient had been treated for a similar dermatitis two years prior to this outbreak, and for the past two years she had not used dye. She had resumed the practice in the hope that her susceptibility had been overcome. It is of interest that for years she has used peroxide and ammonia to bleach her scalp hairs without untoward effects as well as lip rouge,

Fig 2—Pedigree chart of family of piebald Negroes

and 6 were to be seen in 1933 at a Century of Progress Exposition. It was owing to such travels that descriptions of members of this family have found their way into European literature.

Most of these Negroes have married within their own race. In this connection, however, female 6 deserves particular mention. Her father is an Italian. The pigmented portions of her skin are consequently lighter than those of her Negro relatives, but in spite of this her piebald pattern is very similar to that of other members of the family.

It will be noted from an examination of figure 2 that the character is transmitted as a simple dominant unit character, as was shown by Simpson and Castle. Each piebald individual is born of a piebald parent who is heterozygous for the piebald character and transmits it usually to half of his offspring. No normal individual of the family transmits the piebald character. The pedigree chart shows a total of twenty-five piebald Negroes in four generations, the population comprising eighty-five individuals. In ten matings of piebalds with normals there were produced twenty-four piebald and eleven normal offspring. Since equality of each type is expected, it will be seen that the production of piebalds considerably exceeds expectations.

To biologists a dominant mutation of this sort is of interest as showing in the case of man, the occurrence of an inherited pattern of skin pigmentation such as that found in other mammals. Familiar examples are seen in the Dalmatian "coach" dog, the English rabbit, and Hereford cattle. A study of the normal variation within the piebald pattern of this family would be of considerable interest.

Bussey Institution

#### DERMATITIS OF THE EYELIDS

HERBERT RATTNER, M.D., CHICAGO

THE JOURNAL has recently contained several reports dealing with dermatitis of the eyelids caused by eyelash dye. Dermatitis of the eyelids occurs rather frequently; it is usually due to external irritants, but to determine the irritant may be difficult.

An experience with four cases seen within a few days of one another prompts this note. All four patients were women who presented inflammations of varying severity, and the exciting agent in each case was different.

**CASE 1**—A young woman, a manicurist, shown in the illustration applied Godfrey's dye to her eyebrows and eyelashes and within a few hours the lids became swollen and red and itched intensely. When she was seen the next day there was severe conjunctivitis with photophobia and the lids, eyebrow regions and adjacent portions of skin were the seat of an intense vesicular eruption. The skin was edematous and red and she complained of severe pain in the eyes. The eyelashes

were cut off as close as practicable, and the dermatitis was treated with soothing dressings. It required about four weeks for the eruption to heal, and two months passed before she was able to resume her work.

**CASE 2**—A young woman complained of dermatitis of the eyelids of one year's duration. The lids were red and scaly and slightly swollen from rubbing. The dermatitis would improve at times and then flare up, so that in the past year she had never been entirely free from dermatitis. Among the irritants to which she was exposed were cosmetics, artists' supplies, flowers, a fur coat collar and the usual household articles, such as washing soaps and cleaning fluids. After the nature of her trouble was explained to her, she recalled that

Dermatitis from Godfrey's hair dye applied to eyebrows and eyelashes (case 1)

the flareups of her dermatitis followed usually after visits to the hairdressers, where the shampoo was followed by the application of a so-called wave lotion to maintain the waves in her hair. No changes were made in her routine other than to omit the wave lotion from her ritual. The dermatitis cleared up but reappeared when the lotion was again used. She has since had no recurrence of the dermatitis, she is able to pursue her

art studies and her household duties, and she is able to use her other cosmetics without harmful effects

CASE 3—A young woman was seen three years ago for dermatitis of the eyelids, the cause of which was found to be a face lotion that contained camphor. There had been two or three recurrences which the patient herself had been able to trace to various cosmetics. She returned this time with a persistent dermatitis of some two months' duration. The exciting agent was found to be a brown fur coat collar.

CASE 4—A woman of middle age, a patient of Dr. William Allen Pusey, presented a subacute scaly erythematous dermatitis of the eyelids of two weeks' duration. The history suggested that cold cream was the excitant. The patient was skeptical, because she had used this particular kind of cold cream for years. A patch test with the cream, which gave a positive local reaction and a focal flareup, convinced her. Although, as stated, she had used this make of cold cream for years the jar was a new one just recently purchased. It is likely that some new ingredient such as a new perfume had been incorporated by the manufacturers. The patient was not inclined to submit to further studies, she merely discarded the cold cream for another brand.

#### COMMENT

These cases illustrate some important practical facts. In all cases of dermatitis of the eyelids, external irritant must be sought as the exciting agents. Fortunately, most irritants produce mild inflammatory reactions, but they are sufficient usually to cause a great deal of annoyance and some unsightliness, and occasionally, as in the case with dyes, the reactions are so severe as to disable the patient. The nature of the irritant is sometimes self evident, more often it is obscure. But usually the irritant is found to be hair tonic, hair dye or wave lotion, face creams, eye washes, nasal sprays, face powders and rarely spectacle rims. Within a few days I have seen a case in Dr. Pusey's practice in which the dermatitis of the lids and on the nose and above the ears appeared where contact occurred with imitation horn spectacles.

A good intelligent history from a cooperative patient, brought out by pointed questioning, will help to solve more cases than will routine skin tests. When skin tests are necessary the patch test is of the greatest value, for the sensitization in such cases is epidermal. It is in patients who are sensitive to more than one irritant, as in case 3, that patch tests are necessary, or as a confirmatory test as in the fourth case. For routine office procedure, however, it usually suffices to obtain a good history and to outline the problem to the patient, and in most instances an intelligent patient will herself ferret out the etiological agent of her dermatitis.

#### EXCRETORY UROGRAPHY AFTER SUBCUTANEOUS INJECTION OF NEOSKIODAN

EDWIN BEER, M.D., AND FREDERICK H. THEODORE, M.D., NEW YORK

The object of this note is to call attention to a third route for administering chemicals of the new group for excretory urography. In America, apparently, no attempts have been made along these lines, though intravenous and oral administration are well recognized. In 1931 Butzengeiger<sup>1</sup> first attempted subcutaneous skiodan in adults, using a 4 per cent (isotonic) solution and injecting 500 cc containing 20 Gm into the axillae. In thirty cases he reported results almost as satisfactory as those obtained by intravenous injection. The maximum excretion appeared from thirty to fifty minutes after injection, and there were no local or general deleterious effects.

In 1932 Hillebrand<sup>2</sup> used this method in a child of 14 months with a renal tumor in whom intravenous injection was not possible. He used 100 cc of a 4 per cent skiodan solution and obtained good results. The child died after the nephrectomy and autopsy showed no disturbance inflammatory or necrotic at the site of injection in the axillary tissues.

<sup>1</sup> Butzengeiger O. Ausscheidungs Pyelographie (Urographie) durch subkutane Abrodil Infusion. Röntgenpraxis 3: 881-884 (Oct. 1) 1931.

<sup>2</sup> Hillebrand H. Ausscheidungs pyelographie durch subkutane Abrodil Infusion beim Kinde. Zentralbl. f. Chir. 59: 1048 (April 23) 1932.

In the service at Mount Sinai Hospital, fifteen patients—ten children, the rest adults—have been injected in this way with fairly satisfactory results. In this series a 7 per cent neoskiodan solution, approximately isotonic, was used, 50 cc being injected into each axilla, a total dose of 7 Gm. The low toxicity of the substance allows administration of the full dose in infants.

Fig. 1—Intravenous pyelogram showing a horseshoe kidney

The injection is attended by only the usual slight discomfort of a hypodermoclysis, local anesthesia being used for the older patients. In no case was there subsequent tenderness or induration. The best urographic shadows are obtained about fifty to sixty minutes after injection, a compression bag being used,

Fig. 2—Subcutaneous pyelogram of the same case as in figure 1 two years later

although good urograms can be taken at any time from thirty to ninety minutes after injection, so that only one or two plates are necessary. To demonstrate the efficiency of this procedure, two pictures of a horseshoe kidney are reproduced, one taken after intravenous injection and the other after subcutaneous injection of neoskiodan.

## CECAL POLYP ON OCCLUDED BASE OF APPENDIX

ABRAHAM STRAUSS M.D. CLEVELAND

The reason for reporting this case is the unusual location of the polyp. Polyps and papillomas occur in any part of the colon. They may be single or multiple and usually are of inflammatory origin. The case reported here was probably due to repeated attacks of inflammation of the appendix by which the lumen of the appendix became closed off from the cecum. The appendiceal lumen thus enclosed became a source of irritation itself, and the response to this was a reaction of the mucosa on the cecal side of the obliterating membrane in the form of a polyp.

A woman, aged 22, married three years, with a negative family history, has one child, aged 2 years, living and well. The menstrual history was negative. At the age of 15 she had an attack of severe abdominal pain while at a girls' camp. This was diagnosed as appendicitis. Since then, she has had some "bilious" attacks of pain in the lower part of the abdomen, more on the right side, accompanied by vomiting. She used to be confined to bed a day or two with each attack. Thirteen months ago she had a severe attack when I examined her for the first time. This attack was characterized by severe pain in the lower right quadrant of the abdomen, nausea and vomiting. Examination at that time revealed tenderness and slight spasm over McBurney's point. Pelvic examination was negative. The temperature was 99, the pulse 88, and the white blood count 12,000. Because the physical manifestations were still mild enough and because the patient was only nine months post partum, it was decided to be conservative unless the signs grew worse. Thus she was tided over this attack and remained well, with only slight discomfort at times until Dec. 23, 1933, when she had sufficient pain to go to bed. I saw the patient the next day when she was a little better and set the date for operation for December 27 to allow her to have Christmas at home. The physical conditions were the same as one year before. The patient had no other symptoms and the rest of the physical examination was negative.

December 27, resection of the tip of the cecum with the appendix was done. The patient was prepared and draped in the usual manner. McBurney's incision was made. The cecum was secured and the appendix was found to lie in the fossa beneath the cecum. It was short, thick and very firm, almost as if it contained concretions. The appendix was bound down

Fig. 1—Appendix with wall of cecum turned down displaying projecting polyp.

by much thickened indurated tissue, which gave evidence of chronic inflammation. The base of the appendix was very broad and thick and seemed to be the prolongation of a funnel-shaped cecum, as it was not sharply demarcated at the cecum. A polypoid growth about 1 cm in length was palpated, arising from the base of the appendix and projecting into the cecum. The appendix was freed from the surrounding tissue and from the meso-appendix, and the tip of the cecum was crushed with two Kelly clamps proximal to the polyp and severed with the actual cautery. Thus, the tip of the cecum was resected together with the appendix. The cut ends of the cecum were then closed with a Cushing stitch of chromic No. 1 catgut. Closure was further strengthened by serosal sutures of linen. All bleeders had been ligated, and closure was effected in the usual manner.

The preoperative diagnosis was chronic appendicitis. The postoperative diagnosis was chronic appendicitis with a polyp of cecum at the base of the appendix.

A pathologic report was made by Dr. Benjamin S. Kline, pathologist of Mount Sinai Hospital. The appendix and a small portion of the regional cecum were examined. The

appendix was 4.75 cm long and from 2.5 to 8 mm in diameter, gradually enlarging toward the proximal end. The serosa, somewhat thickened, showed sheetlike fibrous tags adherent to the distal half. Attached to the adhesions was a flat, bean-shaped mass about 5 by 4 by 2 mm (lymph node? adipose tissue?). The most striking thing about the specimen was the fact that there was no detectable opening from the appendix into the cecum. Instead, the site was occupied by a polypoid mass about 4.5 mm in diameter and 7 mm long, continuous with the mucous membrane of the cecum. The polyp projected into the cecal lumen. There was some reddish discoloration of the surface of the polyp. On cross section of the appendix about 5 mm from the proximal end, the lumen was distended

Fig. 2—Polyp of cecal mucosa overlying blind base of appendix. The three coats of cecum and appendix can be traced.

by coherent dry fecal material about 7 mm in diameter. When this material was expressed from the proximal portion of the appendix, a cup-shaped depression was observed, and just beyond the blind end lay the base of the polyp already mentioned. On section of the appendix, the lumen obliterated in the tip was elsewhere slightly or considerably distended with coherent dry secretion. There was some reddish flecking of the mucosa throughout. The walls in general stretched. There was perhaps some edema of the inner coats.

The gross diagnosis was old chronic appendicitis of the proximal portion with occlusion of the lumen, distention of the lumen by coherent dry fecal matter, and old adhesions about the distal half of the appendix. There was an overgrowth of cecal mucosa in the region of the previous appendiceal orifice with polyp formation here, early acute appendicitis(?).

Microscopic examination of two sections of the appendix from 7 to 11 mm in diameter showed the lumen to be from 4 to 8 mm distended by coherent fecal material, which in places appeared to continue into the mucosa a small distance with but minimal regional reaction. There was slight scarring and round cell infiltration of the inner coats and some edema of all coats. A third section was about 3 mm in diameter, with no lumen, no glands and no lymphoid tissue in the mucosa. There was some edema of all the coats. A fourth section, including the regional cecum, showed a striking picture. The most proximal portion of the appendix showed complete occlusion of the lumen and fusion of the submucosa of the appendix with the submucosa of the cecum. The appendix in this portion showed a picture similar to the first and second sections, with distention of the lumen by fecal material and a thin mucosa. There was slight scarring and round cell infiltration of all coats. Regional to the occluded appendix there was a polypoid overgrowth of cecal mucosa and submucosa about 4.5 mm in diameter with moderate scarring, considerable round cell infiltration and marked leukocytic infiltration. There were numerous lymph follicles present. There was an area of necrosis and pus cell infiltration and hemorrhage of the mucosa.

of overgrowth several millimeters in extent. There was some carrying and round cell infiltration of the cecal mucosa at the margins of the section.

The final diagnosis was occlusion of the lumen at the proximal end of the appendix and fusion of the submucosa with the submucosa of the cecum, chronic appendicitis (slight) with considerable distention of the lumen and old adhesions about the distal half of the appendix.

## Therapeutics

### THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.  
CHICAGO

NOTE—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—Ed

#### THERAPY OF ERYSIPELAS

##### PROPHYLAXIS

1 Isolation from surgical patients is desirable and from obstetric patients is imperative, but quarantine otherwise is not required. The period of isolation should continue until all local lesions are healed.

2 Disinfection of the hands and of the instruments of physicians and of nurses taking care of a patient with erysipelas is necessary. Even with this precaution, physicians and nurses should not simultaneously attend surgical or obstetric patients. Thorough cleansing suffices for final disinfection.

3 The organisms may persist in the patient for a long time in sinus or nasal discharges, which accounts for the tendency to recurrence in those who have suffered from the disease. In such carriers even the slightest traumatism, especially about the nose, should be prevented as much as possible.

##### TREATMENT

1 *Local*—(a) Ultraviolet irradiation of the area involved and of the normal adjacent skin at least two inches beyond the border should be done. The mercury quartz burner is used. The lamp is run for ten minutes first, so as to work up to maximum efficiency. The rays must be direct, so as to strike the diseased area and adjacent skin at right angles for a duration of ten minutes at a distance of 12 inches. In infants and very young children the time may be reduced to five minutes and occasionally to three minutes. If the area of erysipelas shows evidence of spreading, a second treatment will be necessary. Usually one intense treatment suffices.

(b) Roentgen rays, 100 kilovolts, unfiltered in moderate doses (not over one-fourth erythema dose) should be applied and the application repeated not more than once on the second day, if results have not been satisfactory. It is necessary to include a 2-inch margin of apparently uninvolved skin in order to treat all infected areas. Roentgenotherapy is not advisable in the diabetic, the nephritic and young children.

(c) A barrier consisting of a narrow (three fourths inch) band of contractile collodion (Collodion, U. S. P.)

all round a small lesion may possibly be effective. The band must be applied thickly enough to produce a deep depression about 2 inches from the margin.

(d) Evaporating lotions, applied ice cold by means of uncovered compresses, give relief to the hot burning sensation, which may be still better ameliorated by the addition of 1 per cent phenol. The Solution of Aluminum Acetate, diluted 1/8, is preferable for moist areas. If ulcers develop, these should be treated in accordance with the principles laid down in "Ulcer Therapy."

2 *Erysipelas Antiserum*—Administration of erysipelas antiserum should be preceded by an intracutaneous test of 0.1 cc. of the serum diluted 1/10. If the test is negative within fifteen minutes, one may inject the remainder of the contents of the ampule. The dose may be repeated daily for three days. If the test is positive, it might be well to use convalescents' erysipelas serum rather than the serum derived from the animal, in amounts varying from 40 to 100 cc.

3 *Fever Regimen* (q. v.)—Restraint is not infrequently necessary, as acute delirium may supervene. Protection of the patient should consequently be provided.

4 *Symptomatic Treatment*—A hypnotic may be required for obstinate insomnia (q. v.) or stimulation for collapse (q. v.)

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT  
H. A. CARTER, Secretary

### SOURCES OF ULTRAVIOLET AND INFRA-RED RADIATION USED IN THERAPY

#### PHYSICAL CHARACTERISTICS

W. W. COBLENTZ, PH.D., D.Sc.  
WASHINGTON, D. C.

It seems as though there has never been such a widespread attempt as today to foist on an unsuspecting and trusting public all sorts of alleged physical cure-alls to relieve people's ills and to keep them in health. Prominent among these panaceas is the exploitation of ultraviolet and infra-red rays. The mere mention of "infra-red rays" creates in the mind of many persons a feeling that this is something new and mysterious that they have missed, when, as a matter of fact, it is difficult to think of a warm object that does not emit infra-red rays.

When an object is heated to a higher temperature than its surroundings, an excess of infra-red rays passes from it to the surrounding objects. Examples of sources of infra-red rays are arc lamps, incandescent lamps, coal fires, steam pipes and hot stoves. Because of their low temperature, the infra-red rays emitted by hot water bags and electrical heating pads are of low intensity, and hence they are insignificant in comparison with the amount of heat that is obtained by conduction, by having the hot pad or hot water bottle in contact with the body. Of course it sounds more impressive to speak of infra-red rays than to speak of the application of heat by conduction, by direct contact of the pad with the body.

There is nothing new or mysterious about the ultra-violet and the infra-red rays. A person is always exposed to the infra-red rays when standing near a steam radiator, an open grate fire or even an electric toaster. The spectral quality and total intensity of the infra-red rays emitted by the radiant heaters for warming rooms is essentially the same as emitted by the infra-red lamps sold for therapeutic purposes except that the latter have smaller reflectors and have more elaborate adjustable mountings, which cost more money.

During the past few years, experimental data have become available showing that the spectral band of ultraviolet radiation of wavelengths shorter than about 3,150 angstroms,<sup>1</sup> occurring in sunlight and in some artificial sources of radiation, if sufficiently intense and if the time of exposure is sufficiently prolonged, has the power of preventing and of curing rickets. This is the underlying basis for exploiting ultraviolet of these wavelengths for general healing purposes. While this point of view may be too broad, the beneficial effects of short wavelength ultraviolet radiation in surgical tuberculosis and certain skin diseases is recognized.

Before I discuss the various types of sources of radiation available for therapeutic purposes, it will be instructive to consider several incidental questions that enter into the subject. In fact, in order to apply radiation therapy successfully, it is important to have a thorough understanding of the physical properties of the source of thermal radiation as well as the physiologic reaction of living matter when exposed to it. Successful phototherapy depends on a knowledge of the spectral quality of the source, the total quantity or intensity, and the time of exposure, which depends on the distance of the patient from the lamp.

Excepting for the question of intensity and wavelength, physically there is no marked distinction between the various regions of the spectrum called "ultraviolet," "visible" and "infra-red." Chemically and physiologically there is a distinct difference. The action of infra-red rays is thermal and instantaneous, producing a burning sensation when the intensity is too great. On the other hand, the ultraviolet rays are actinic, causing, among other effects, the coagulation and precipitation of albumin. Their action is slow and insidious, so that the effect is not perceived until from three to six hours after exposure. A short exposure to an innocent-looking carbon or mercury arc may produce severe conjunctivitis. Hence the eyes should be protected with deep brown glasses or covered with a black cloth to prevent injury when the body is being irradiated.

Although there is no sharp demarcation of these rays into wavelength bands, for convenience I shall indicate these spectral ranges (table 1) and mention some of the photochemical and physiologic effects, if known. The wavelengths may be written in angstroms, microns ( $\mu = 0.001 \text{ mm}$ ) or millimicrons ( $m\mu$ ), i. e., wavelength  $3,000\text{A} = 0.3 \mu = 300 m\mu$ . Thus the ultraviolet emission line of the quartz mercury vapor arc lamp, frequently mentioned in this paper, is 2,967 angstroms, 0.2967 micron or 296.7 millimicrons. More complete data on the radiation from arc lamps<sup>2</sup> and on their germicidal action<sup>3</sup> are given in other publications.

**1 Depth of Penetration of Thermal Radiation**—Authorities differ as to the depth of penetration of radiation of different wavelengths into the human body. Eventually this may not be an important question, but it may serve to explain why discomfort is sometimes experienced when one is exposed to certain types of lamps, owing to the emission of an excessive amount of infra-red radiation of wavelengths that cannot penetrate deeply into the skin.

In passing it is instructive to note that the shortest, "hard" x-rays and longest radio waves are deeply penetrating. It is therefore of interest to summarize what is known about the transparency of the skin and the blood to radiation of various wavelengths throughout the spectrum.

Data on the depth of penetration of radiation into the skin are given in table 1. It is, of course, to be understood that small amounts of radiation penetrate to still greater depths than here indicated and that these values represent limits in depth at which effective biologic action may still be expected. In the dehematized skin

TABLE 1—*Different Spectral Regions, Probable Depth of Penetration and Probable Physiologic Action of Rays from Different Sources\**

Spectral Region	Penetration of Rays	Physiologic Action	Source
Far ultraviolet 1,800 to 2,900 A	Superficial 0.1 to 0.5 mm	Photochemical	Metals in carbon arc and spark of metals (mercury arc)
Near ultraviolet 2,900 to 3,650 A	Superficial 0.5 to 1 mm	Photochemical	Sun, metals in carbon arc, arc of metals
Visible spectrum 3,800 to 7,600 A	Superficial 1 to 5 mm	Thermal nerve stimulation	Sun, carbon arc
Near infra red 7,600 to 10,000 A	Deep 10 to 30 mm	Thermal nerve stimulation	Sun, carbon arc, gas filled tungsten lamp
Far infra red 15,000 to 150,000 A	Superficial 3 to 0.1 mm	Thermal nerve stimulation	Carbon arc infra red (radiant) heaters

\* Wavelengths in angstroms, A.

the depth of penetration would be greater than under normal conditions.

**2 Reflectors and Windows**—In view of the fact that most lamps used for therapeutic purposes are provided with reflectors and windows, it is relevant to emphasize the fact that the mirror acts solely as a reflector of the rays that fall on it and does not itself contribute anything additional to the ultraviolet radiation emitted by the source. In fact, since the reflector absorbs more of the short wavelength ultraviolet than of the visible and infra-red rays, especially when the surface is composed of a powdered metal (for example, aluminum) which has been applied with a lacquer, the total amount of ultraviolet radiation in proportion to the visible and the infra-red rays is relatively lower in the reflected rays than in those that proceed directly from the source. The reflector, placed back of the source, simply increases the total amount of radiation of all wavelengths falling on an object placed in front of the lamp. The reflector cannot supply ultraviolet wavelengths that may be lacking in the source, and after it becomes covered with smoke from the arc, the amount of reflected radiation is, of course, greatly reduced.

Likewise windows or filters used in front of the source of ultraviolet, whether it is the sun, the mercury arc or the carbon arc, emit no ultraviolet wavelengths

<sup>1</sup> The angstrom unit of wavelength is one ten millionth millimeter.

<sup>2</sup> Coblenz, Dorcas and Hughes. *Bur. Stds. Sc. Papers* 21: 535 (1926) (Nos. 539, 15 cents). The Bureau of Standards publications are obtainable only from the Superintendent of Documents, Washington, D. C., at the prices indicated.

<sup>3</sup> Coblenz and Fulton. *Bur. Stds. Sc. Papers* 19: 641 (1924) (No. 495, 20 cents).

themselves but always reduce the intensity of the rays that are present. The same is true of lacquers used in applying the powdered metal for a reflecting surface. Linseed oil and cellulose lacquer are highly opaque to ultraviolet radiation of wavelengths shorter than 3,500 angstroms.

**3 Radiant Heat Versus Conducted Heat**—Owing to the general misconceptions on this subject, it is relevant to call attention to the difference in heat transfer by conduction and by radiation. Practically all the heat obtained from an electrically operated heating pad or a hot water bottle (which takes the place of a heated brick or of ground meal used in the earlier days), placed in contact with the body, is transferred by thermal conduction. The amount obtained in the form of infra-red rays is negligibly small.

#### SOURCES OF RADIATION

Under the caption of sources of radiation, various types of thermal radiators are considered, beginning with those operated at low temperatures and therefore emitting principally infra-red rays. In order to obtain an appreciable amount of ultraviolet radiation it is necessary to heat the radiating substance to a high temperature, 3,000 C (5,432 F) or higher. Since solids (e.g., metals such as tungsten) evaporate rapidly at high temperatures, sources of ultraviolet radiation are practically confined to electric arcs between electrodes of metals, of carbon, and of mercury vapor in a closed tube of quartz glass called "the burner."

**1 Miscellaneous Sources**—Under this caption may be grouped vacuum incandescent lamps, kerosene lamps, acetylene flames, luminous and Bunsen gas flames, and incandescent mantles heated by gas flames, which do not emit sufficient ultraviolet radiation to be useful in therapy. Neither is the ultraviolet emitted of sufficient intensity to be a source of injury to the eye. Vacuum incandescent lamps have been built into cabinets used for treatment by means of infra-red rays. Wood and coal fires, in an open grate, emit practically no ultraviolet radiation but are good sources of infra-red rays, which will become less and less familiar to coming generations. The open front gas stove, with its incandescent radiant of refractory clay, cannot be operated at a sufficiently high temperature to emit an appreciable amount of short wavelength ultraviolet rays. It is a convenient source of intense infra-red radiation, giving a spectral energy distribution that is somewhat similar to curve B in chart 1 provided care is taken to avoid the production of carbon monoxide which results from improperly adjusted gas burners and insufficient ventilation.

**2 Infra-Red Radiators**—Under this caption may be placed various radiant heaters used for therapeutic purposes. They consist of a concave reflector at the focus of which is an incandescent filament lamp in a glass bulb, or a heater consisting of an electrically heated solid rod, or a resistance wire embedded in or wound on an electrically nonconducting, refractory material, such as, for example, steatite, "lava" or porcelain. The color of the surface (whether white or black) is unimportant. The nonmetallic surface emits the greatest amount of infra-red rays.

The incandescent filament radiators that are enclosed in glass bulbs emit radiation of wavelengths 5,000 to 40,000 angstroms (chart 1), with the maximum emission at from 11,000 to 20,000 angstroms depending on

the temperature of the filament. Only a small amount of radiation is emitted by the glass bulb.

The radiant heaters that are not enclosed in glass emit perceptible radiation of all wavelengths throughout the infra-red to 150,000 angstroms (15  $\mu$  in the illustration), beyond which point the intensity is very low, as shown in chart 1. The carbon dioxide and water vapor in the air selectively absorb certain wavelengths in the infra-red, producing indentations in the spectral energy curves, especially at 4.2 microns (42,000 angstroms), as shown in this illustration. With increase in temperature the maximum emission shifts toward the short wavelengths, so that for a surface temperature of from 300 to 400 C (572 to 750 F) the maximum emission (curve C, chart 1) is not well defined, extending from 4 to 5 microns (40,000 to 50,000 angstroms), whereas at a low red heat (from 600 to 800 C, or 1112 to 1472 F) the maximum emission becomes more sharply defined (curve B, chart 1) and lies between 2 to 3 microns (20,000 to 30,000 angstroms). Moreover, the infra-red radiation from the latter is far more intense (eight to ten times greater) than that emitted by the heater at 300 C (572 F).

Chart 1—Infra red radiators

The reflectors surrounding these heaters are practically nonselective, hence they have no appreciable effect in modifying the spectral composition of the radiation emanating from the heater. In other words, there is no way of producing narrow spectral zones of radiation by emission in the infra-red. On the other hand, filters for isolating relatively narrow bands of the visible and ultraviolet are easily provided.

For experimental purposes, the most easily produced, fairly narrow band of infra-red radiation is obtainable from the Bunsen nonluminous gas flame, which has a strong emission band at 4.4 microns (44,000 angstroms), but the total intensity is rather low.

A filter consisting of a cell of water and red glass will confine the radiation stimulus to the spectral region extending from 6,000 to 14,000 angstroms. The red glass alone will confine the stimulus to wavelengths between 6,000 and 40,000 angstroms. Such a filter may be used in front of a Mazda, gas-filled tungsten lamp as a source of infra-red rays.

As already mentioned, these radiant heaters, made for therapeutic purposes, do not differ in principle from those used for heating dwellings, except that the latter have a wider pan or hood for reflecting the rays over a wide area, while in the therapeutic radiator the reflector projects the radiation on a small area.

3 *The Tungsten Filament Lamp*—The "Mazda" tungsten filament lamp, enclosed in a bulb of special glass that transmits ultraviolet at wavelengths extending from 2,800 to 3,100 angstroms (recognized as effective in preventing rickets) has been considered for a source of ultraviolet radiation. A small lamp, similar in appearance to the automobile headlight lamp, was on the market some time ago. It was operated at a considerably higher voltage than that normally used, which shortened the useful life to a few hours. It was claimed that under these conditions the lamp would emit sufficient ultraviolet radiation for therapeutic purposes. The

Chart 2—Spectral energy (intensity galvanometer deflections) distribution of the radiation emitted by the arc between electrodes of nickel of tungsten and of mercury vapor in a quartz tube called the burner

lamps examined did not emit an appreciable amount of ultraviolet rays of wavelengths less than 3,100 angstroms.

Calculations and radiometric measurements show that the tungsten filament lamp, even when enclosed in a bulb that transmits the ultraviolet rays extending from 2,800 to 3,100 angstroms, emits but little ultraviolet radiation of these wavelengths.

In curve A of chart 1 is depicted the relative special energy distribution of the radiation from the gas-filled tungsten lamp. The maximum emission occurs at 10,600 angstroms ( $106 \mu$  in the illustration). The measurements were made on a 1,500 watt gas-filled lamp, but without a reflector such as is used in a therapeutic lamp. The reflector would increase the total intensity in the direction observed. The bulb, which was of clear glass, absorbs practically all the radiation of wavelengths longer than 35,000 angstroms and it absorbs completely all the radiation of wavelengths greater than 45,000 angstroms. The low temperature radiation from the heated glass bulb (some 11 per cent of the total) cannot penetrate deeply into the skin.

The gas-filled tungsten lamp is useful as a source of visible and of short wavelength infra-red radiation of wavelengths less than 15,000 angstroms. About 30 per cent of the total radiation emitted by the gas-filled tungsten lamp is of wavelengths that can penetrate deeply into the skin. The original papers cited here<sup>4</sup> contain data on the spectral energy distribution of the tungsten filament in a gas-filled bulb.

4 *The Violet Ray Lamp*—One of the standard products of commerce is an incandescent lamp consisting of a helical carbon filament in a bulb of blue glass, sold for decorative purposes and sources of low illumination in assembly rooms. If such lamps have a therapeutic effect, e. g., in stimulating the growth of hair on bald heads, it should be noticeable on patrons of amusement houses. Nevertheless such lamps have been put into special caps and sold for growing hair and for therapeutic purposes.

Radiometric tests showed that the intensity of the violet and ultraviolet rays emitted by such a lamp is only one ten-thousandth the total radiation emanating from the lamp. The amount of violet and ultraviolet rays of full sunlight transmitted through the glass bulb of such a lamp was from 1,000 to 1,500 times greater than that of the carbon filament lamp. Observations showed that the intensity of the violet rays of sunlight (skylight) falling on the scalp of a person sitting near a window, but not in direct sunlight, would be from 50 to 150 times that of a blue bulb carbon filament lamp.

Another bit of hokum is a so-called violet ray lamp, consisting of a spark coil to which is attached a glass tube that terminates in a flattened glass bulb, which emits a blue glow when it touches the body. The function of this glass tube is to provide a high resistance to the electric current that comes from the spark coil, so that the patient will not feel the shock too severely, and even if the ultraviolet rays generated could pass through the glass walls of the bulb, they would be too weak in intensity to be effective for therapeutic purposes.

5 *The Nickel and the Tungsten Arc*—The radiation emitted from the arc vapors between two electrodes of nickel, and of tungsten, consists of numerous fine lines which (chart 2) are not separated when examined with a small spectroscope.

The spectral energy distribution of the arc between two pure nickel rods, 12 mm in diameter, with tapered ends, operated on 6 amperes, is given in figure 2, from which it may be noted that the nickel arc emits strongly at 230 millimicrons (2,300 angstroms) and especially at 350 millimicrons (3,500 angstroms). These bands are especially conspicuous in certain cored carbons, discussed in a subsequent part of this chapter. The arc of nickel-cord carbons is an excellent source of ultraviolet radiation. Moreover, the material is inexpensive, quiet burning and easy to operate.

Chart 3—Spectral energy (intensity) distribution of the sun and of the carbon arc

The tungsten rods examined were 64 mm in diameter and were the regular imported British stock material used for therapeutic purposes. They were operated on 5 amperes. Because of the formation of a crust of oxide around the electrode, the arc was rather unsteady and hence difficult to operate. The emission spectrum of tungsten is weak in the spectral region of wavelengths shorter than 2,300 angstroms (230 mμ in the illustration).

The odors from the metal arcs are disagreeable, and some vapors may be irritating to the bronchial tubes. In order to eliminate the odors and to secure greater

4 Coblentz W W Bur Stds Sc Bull 14 115 1917 (No 300 5 cents) Priest Bur Stds Sc Papers 18 225 1922 (No 443 5 cents)

steadiness in operation, coiled carbon electrodes containing oxides of certain metals are commonly used in place of electrodes of pure metals

**6 The Sun**—In connection with the following discussion of the radiation emitted by artificial sources, it is relevant to mention the sun—the only natural source available for therapeutic purposes. The temperature of the surface of the sun is above  $5\,500\text{ C}$  ( $9\,932\text{ F}$ ), some estimates being  $6\,000\text{ C}$  ( $10\,832\text{ F}$ ). The solar radiation intensity, falling on a surface normal to the incident rays in this latitude ( $38^{\circ}\,50'$ ) at sea level at the noon hour on a clear day, amounts to about  $1\,2\text{ Gm-calories per square centimeter per minute}$  and rarely rises to  $1\,35\text{ Gm-calories}$ . Less than  $0\,1$  per cent of this amount is ultraviolet of wavelengths that have a strong therapeutic action, at least in preventing rickets.

The intensity of the ultraviolet rays varies greatly with the altitude above sea level (chart 3) and also with the time of day. Only between the hours of  $9\text{ a m}$  and  $3\text{ p m}$  (excepting in the three summer months, when least needed) is this ultraviolet component of sufficient amount to be of importance radiometrically, and probably therapeutically. In addition to this variation with the time of day, the amount of vitalizing ultraviolet solar rays available for therapeutic purposes varies with the season of the year, with the altitude and the geographic latitude of the station, and with the almost infinite variety of air pollution and weather conditions that are encountered in different localities.

The intensity of the shortest ultraviolet solar rays transmitted by the atmosphere is extremely small. The intensity at  $2\,900$  angstroms is only one millionth as great as at  $3\,130$  angstroms, where the mercury arc has a strong emission line, and only about one forty-millionth of the intensity of the sun's rays in the visible spectrum, where the intensity is a maximum (chart 3).

**7 The Carbon Arc**—As already mentioned, the temperature of the surface of the sun is about  $5\,500\text{ C}$  (about  $9\,900\text{ F}$ ). The temperature of the positive electrode of the carbon arc is much lower—about  $3\,300\text{ C}$  (about  $6\,000\text{ F}$ ). The carbon arc is the hottest artificial source of radiation readily obtainable, and in this respect it is the closest approach to sunlight. However, the radiation from the carbon arc is far from being like sunlight. There is a strong emission band in the violet at about  $3\,890$  angstroms (the "cyanogen band," chart 3), and beyond  $40\,000$  angstroms in the infra-red there is a great amount of radiation not present in sunlight. When a window of special glass (e g, Corex-D) is used, which shuts out the ultraviolet rays of wavelengths shorter than  $2\,900$  angstroms and longer than  $40\,000$  angstroms, the spectral limits are similar to those of sunlight, but the intense cyanogen band remains.

Except for the violet cyanogen band at  $3\,890$  angstroms, the vapors from the electrodes of pure carbon are quite nonluminous. A highly luminous arc is produced with carbons filled with various substances.

Superimposed on the radiation from the arc vapors is the continuous spectrum from the highly incandescent crater of the positive electrode. The result is an intense infra-red spectrum, of wavelengths longer than the solar rays transmitted by the atmosphere. If the arc is surrounded by a glass or a quartz globe, as already mentioned, some of the infra-red rays are excluded, but in turn the surrounding globe becomes heated and

emits nonpenetrating infra-red rays with wavelengths of from  $50\,000$  to  $120\,000$  angstroms, which are not present in sunlight. Hence, no exact comparison can be made between the radiation from the sun and the carbon arc.

The crater of the positive electrode emits an intense white light, which, as already mentioned, is mixed with the radiation of the arc vapors. This fact is usually overlooked in discussions of the radiation from the carbon arc. The vapors from the pure carbon arc contribute but a small amount to the total radiation emitted.

In chart 3 is shown the distribution of energy in the ultraviolet and in the visible spectrum of the sun (as observed on Mount Wilson) and of the white flame carbon arc. For convenience in making these comparisons, the radiation intensities (the galvanometer deflections) of the sun and of the carbon arc were set to equality at  $300$  millimicrons ( $3\,000$  angstroms), a procedure that is permissible and in common use.

No appreciable radiation of the sun of wavelengths less than  $2\,900$  angstroms is transmitted by the earth's atmosphere. On the other hand, radiation of wave-

Chart 4—Spectral intensity (energy) curves of different kinds of carbon electrodes

lengths out to  $2\,200$  angstroms is observable in the white flame carbon arc. As illustrated in chart 3, the ultraviolet cyanogen band, with its maximum emission at  $389$  millimicrons ( $3\,890$  angstroms), is relatively far more intense than similar wavelengths in the spectrum of the sun. On the other hand, under the same conditions, the radiation of the sun in the visible spectrum is relatively far more intense than that which obtains in the white flame carbon.

As will be mentioned presently, the radiation from the mercury vapor arc in a quartz burner consists of a series of strong emission lines, notably at  $2\,570$ ,  $2\,650$ ,  $2\,804$ ,  $2\,967$ ,  $3\,020$ ,  $3\,130$ ,  $3\,340$  and  $3\,650$  angstroms. In this spectral region the radiation from the vapors of the carbon arc consists of numerous fine lines, which are so close that the spectrum appears continuous and, hence, somewhat like that of sunlight.

When the carbon arc is enclosed with a close-fitting transparent quartz chimney, the gases surrounding the arc expand and force sufficient air out of the chimney to establish an equilibrium in pressure, viz, atmospheric pressure. The amount of oxygen is reduced and the life of the electrode is prolonged. When the arc is extinguished, cold air rushes in. This does not mean, however, that the arc was operating under reduced pressure, i e, in a partial vacuum. The pres-

sure was the same as or slightly above the atmospheric pressure, but the volume of oxygen (air) was reduced.

In some recent designs of carbon arc lamps the arc is partly surrounded by a metal casing, which reduces the air circulation and prolongs the life of the electrode.

**Factors Affecting Carbon Arc Radiation** It has been found that the radiation from the carbon arc depends on (1) the size and the kind of the electrodes (white flame, blue flame, yellow flame, red flame, chart 4), (2) the direction of the current when direct current is used through combinations of neutral cored and impregnated carbons, and (3) the amount of electric current.

This information has been of assistance in making improvements in arc lamps. Assuming that the manufacturer has incorporated into his lamp the latest improvements based on the information available regarding the proper current, the proper size of electrode for a given current, and the direction of the current (if direct current) through the electrodes, it is incumbent on the purchaser of such a lamp to operate it as was intended. This is evident from the increase in the intensities (galvanometer deflections) of the different wavelengths with increase in the current (hence the temperature) in the arc (chart 5). These curves are called "isochromatics," meaning at some particular wavelength.

Amount of current. Take for example the curve of intensities for the wavelength 3,020 angstroms, which is of special interest because of its strong antirachitic action. On 5 amperes the galvanometer deflection was hardly perceptible. With a current of from 25 to 30 amperes, the intensity (galvanometer deflection) was almost 100 times greater.

**Size of electrodes** Suppose the operator is using carbon electrodes about 12 mm in diameter, which require from 25 to 30 amperes in order to attain the proper temperature. It is evident that on 10 amperes he would obtain less than one-tenth the intensity available. Moreover, the arc would sputter and would burn unsteadily. To avoid the sputtering, the electrode of the carbon arc lamps, with a current of from 8 to 10 amperes, should be only from 6 to 8 mm in diameter.

As a general rule, high amperage arcs are more efficient than the low amperage arcs in the production of ultraviolet and visible radiation, relative to the total infra-red radiation produced. All carbon arcs emit considerable nonpenetrating infra-red radiation of wavelengths longer than 40,000 angstroms not present in sunlight. Aside from the production of a sensation of warmth, there is probably no important physiologic reaction that could not be produced by the above-described, simpler sources of infra-red radiation.

Data on the radiation from the carbon arc have been published elsewhere.<sup>5</sup> To simplify the discussion, it will be sufficient to depict the spectral energy distribution of representative samples of cored carbons containing substances that, in the state of incandescent vapor, have bands of selective emission in certain parts of the spectrum. These spectral energy curves, throughout the ultraviolet, the visible spectrum (from 390 to 750 millimicrons, 3,900 to 7,500 angstroms) and to 800 millimicrons (8,000 angstroms) in the infra-red spectrum, are illustrated in figure 4. The inset on the left-hand side of figure 4 gives a magnified (ten times) illustration of the intensities extending from 250 to 300 millimicrons.

**Direction of current** The carbon electrodes used were 127 mm in diameter and were operated on 30 amperes, alternating current. The effect of direct current is to raise the temperature of one electrode considerably higher than the average that obtains when alternating current is used. This increases the intensity of the cyanogen band at 3,890 angstroms, especially in the blue flame arc, but it does not have so marked an effect on the intensity of the radiation in the short wavelength ultraviolet and in the visible spectrum.

**Kind of electrodes** It may be noticed (chart 4) that in the neutral core carbon arc (a practically pure carbon) the ultraviolet radiation of wavelengths less than 320 millimicrons (3,200 angstroms) is extremely weak, the radiation being concentrated almost entirely in the cyanogen band, with a maximum at 389 millimicrons (3,890 angstroms). In contrast, in the blue flame ("therapeutic B") carbon arc, the ultraviolet radiation of wavelengths less than 310 millimicrons (3,100 angstroms) exceeds that of all the other arcs illustrated (chart 4).

In the yellow flame ("therapeutic C") carbon arc there is considerably more radiation, extending from 2,900 to 3,200 angstroms (290 to 320 m $\mu$  in the illustrations) in the ultraviolet, which is weak in the neutral core carbon arc. In the visible spectrum there is a strong emission extending from 5,000 to 7,500 angstroms.

The red flame ("therapeutic E") carbon arc is conspicuous for its intense emission, extending from 5,500 angstroms in the orange to beyond 7,500 angstroms in the red.

The white flame ("therapeutic A") carbon arc is conspicuous for its relatively low spectral emission in the ultraviolet of wavelengths shorter than 2,900 angstroms, its high emission in the region extending from 4,500 to 5,000 angstroms, which is lacking in the other carbon arcs just described. Owing to the intense radiation in the cyanogen band at 3,890 angstroms (chart 3), the color of the light emitted by the white flame carbon is a more bluish white than sunlight. However, as already mentioned, when the arc is covered with a suitable glass chimney, which absorbs the ultraviolet rays shorter than 2,900 angstroms and the infra-red rays longer than 40,000 angstroms, the white flame carbon arc is the closest approach to sunlight. But it is still far from being an exact match with sunlight in spectral energy distribution. It remains to be determined whether this difference in spectral energy distribution is of importance biologically.

## Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING  
GENERAL DECISIONS  
RAYMOND HERTWIG Secretary

### ACIDOSIS CLAIMS IN LAY ADVERTISING

Acidosis and acid claims, and the words 'acidosis,' 'acidity' and 'acid' are frequently used in advertising to play on vague fears of the public. The usual well-balanced diet includes many alkali yielding foods—milk in its various forms, fruits and vegetables. Acid forming diets are not a practical nutritional problem because a good modern mixed diet adequate in minerals and vitamins can scarcely be potentially acid. It is appropriate to call attention to the fact that certain foods are potentially alkaline, or yield alkaline mineral residues in the body.

Acidosis is a medical name for a morbid condition of diminution in the reserve supply of fixed alkali in the blood and body fluids. Most people have no conception of the true meaning of the word and are quite likely to confuse it with gastric hyperacidity or "acid stomach" or to conceive of it as "acid blood," a condition which would be incompatible with life. The term "acidosis" is so little understood that its use in any advertising except that restricted to the medical profession is misleading and consequently disapproved.

### VITAMIN E CLAIMS FOR PUBLIC ADVERTISING

There are at present no adequate scientific data establishing the role of vitamin E in human dietetics. This vitamin is present in many common foods, the necessary amount so far as is known, being acquired with any ordinary diet. Statements or claims referring to vitamin E in advertising to the public imply a need for special sources of the vitamin that is not warranted by present knowledge. Claims for vitamin E, therefore, other than mere statement of its presence should not be used on food labels or in advertising to the public.

### VITAMIN FORTIFICATION OF FOODS

Tentatively no objection is taken to the reasonable fortification of food products, whether intended for special diets, convalescents or general use, with vitamin concentrates or with natural foods rich in vitamins. There is no convincing evidence, however, that fortification of foods generally serves any public necessity or that it is in the best interest of public welfare, therefore such practice is not to be encouraged.

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

#### ALPHA-LAC

**Manufacturer**—Alpha Milk Laboratories, Sacramento, Calif.

**Description**—A spray dried homogenized mixture of skim milk, lactose dextrose, coconut oil, cacao butter and cod liver oil.

**Manufacture**—The milk used is grade A as produced under the dairy laws of California and the health regulations of the city of Sacramento. The acidity as received at the plant is about 0.13 per cent lactic acid, the average bacteria count is less than 10,000 per cubic centimeter.

As soon as received the milk is drawn into the vacuum pan without preheating, where it is condensed to about 18 per cent solids content at a temperature below 54 C. The condensed milk with the other formula ingredients is pasteurized

for thirty minutes at 62 C. The mixture is homogenized and spray dried at as low a temperature as is practical (82 C). The dry powder is quickly cooled and packaged. In the course of the entire operation the ingredients are in contact with stainless steel or glass.

#### Analysis (submitted by manufacturer) —

	per cent
Moisture	1.1
Ash	2.5
Fat (ether extract)	28.4
Protein (N X 6.38)	11.3
Crude fiber	0.0
Carbohydrates (by difference)	56.7
Titratable acidity as lactic acid	1.1

**Calories**—5.3 per gram 151 per ounce

**Claims of Manufacturer**—A food for infants to be used in place of breast milk when mother's milk is not available, under the directions of the physician. Contains 2 U S P (1934, Revised) vitamin D units per gram.

#### CELLU JUICE-PAK SLICED PINEAPPLE

**Distributor**—The Chicago Dietetic Supply House, Inc., Chicago.

**Packer**—Hawaiian Pineapple Company, Ltd., San Francisco.

**Description**—Processed, peeled and cored sliced pineapple packed in undiluted juice without added sugar.

**Manufacture**—The method of manufacture is essentially the same as for Doles 1, 2 and 3 Hawaiian canned pineapple products. THE JOURNAL, April 8, 1933, page 1106. Partially neutralized unsweetened juice is used to fill the cans.

#### Analysis (submitted by distributor) —

	per cent
Moisture	83.7
Ash	0.4
Fat (ether extract)	0.1
Protein (N X 6.25)	0.3

Carbohydrates other than crude fiber (by difference)	15.2

**Calories**—0.6 per gram 17 per ounce

**Claims of Manufacturer**—Packed in undiluted pineapple juice without added sugar.

#### STOKELY'S FOR BABY SPECIALLY PREPARED STRAINED CARROTS

SEASONED WITH SALT

**Manufacturer**—Stokely Brothers & Company, Inc., Indianapolis.

**Description**—Strained carrots, seasoned with salt, largely retaining the natural vitamins and minerals.

**Manufacture**—Selected, fresh carrots are washed, peeled, steamed in a closed kettle, sieved in a steam atmosphere, canned and processed as described for Stokely's Strained Green Beans, (THE JOURNAL, May 26, 1934, p 1763).

#### Analysis (submitted by manufacturer) —

	per cent
Moisture	89.7
Total solids	10.3
Ash	0.9
Sodium chloride	0.3
Fat (ether extract)	0.04
Protein (N X 6.25)	1.1
Reducing sugars as dextrose	3.0
Sucrose (copper reduction method)	2.2
Crude fiber	0.8
Carbohydrates other than crude fiber (by difference)	7.5
Alkalinity number (cc normal acid per gram ash)	8.1
ph	5.1

**Calories**—0.3 per gram 8.5 per ounce

**Vitamins**—The natural vitamin content is retained in large measure in the manufacturing process by the use of equipment and procedure which exclude incorporation of air, the vegetable material is exposed to steam only.

**Claims of Manufacturer**—Supplementary to the infant milk diet, and valuable for children and adults on soft diets. Has smooth consistency and supplies desirable bulk without roughness. The straining renders the nutrient content readily available for digestion. Scientifically prepared to retain in high degree the natural flavor, mineral and vitamin values. Seasoned to bring out full flavor and packed in enamel lined cans. Requires only warming for serving.

## RATIONAL DIETARY ADVICE

In the knowledge of nutrition there have been great advances of late, which are destined to have an important influence on practical dietetics and dietotherapy, but the responsibility—and the opportunity—for promoting, expounding and applying the novelties have been left largely in the hands of nonmedical persons. Many of the latter are well tutored, understanding students of the science of nutrition and have proved themselves to be capable in leadership. This is true of many of the devotees of modern home economics. On the other hand, the quack and even the well meaning faddist have been quick to seize the opportunities that a more critical medical attitude would tend to thwart. Consequently, as a result of the propaganda of various food faddists, commercial or otherwise, Bogert<sup>1</sup> points out, competent and sane advice about food has been a good deal discredited, since the average person does not appear to be able to discriminate between those who know what they are talking about and those who do not. A great many people therefore attach themselves, Bogert adds, to one of the following groups: (1) those who pooh-pooh all advice about diet and eat whatever they want with indifference or with defiance, (2) those who become overanxious concerning food and often overcredulous as to food theories, so that they try all the advice they can get, either at one time or in series, ending up in a sad state of mental confusion, and (3) those who become zealots, adopting some particular food fad and sticking to it with a perseverance that would be admirable in a better cause.

One of our contemporaries<sup>2</sup> has incriminated the physician to some extent for the sorry situation that prevails. The practice of medicine has always been rife with ideas, fads and fancies about diet. This was true of the medicine of the ancients, the tribal witch doctors and the American Indian medicine men. While simple concoctions of herbs, berries, roots, leaves and

flowers characterized the earlier attempts at nutritional therapy, extreme complexity marks present practices because of the many discoveries in the science of nutrition and the resultant stimulation of food fads and misconstrued theories that defy extermination. The physician, since his advice carries weight with his patients, has been blamed not only for the perpetuation of many old ideas about nutrition but also for the adoption of many of the present unsound dietary practices and food fads. Among the topics for criticism are the unwarranted attacks on meat because it is "hard on the kidneys," the "magic password autointoxication," and the "psychically pandemic acidosis."

To combat the unfortunate situation that has been described, the *Journal of the American Dietetic Association* offers a constructive plan. It suggests that occasional joint meetings of physicians, especially internists, together with dietitians, nurses and biochemists, and physiologists who may be interested, should promote the health dissemination of the newer knowledge of nutrition. Then the essentials for the foundation of a normal diet for persons in good health, and the requisite changes for persons with various illnesses, would become better known to all physicians, nurses and dietitians. Scientific articles on nutrition should replace the syndicated food fad columns in daily papers and discourage the adoption of fanatical and pseudoscientific diets.

## STEROLS IN MILK

Milk possesses a unique value in nutrition. An ideal food for the infant, it still remains the cornerstone around which dietaries are effectively built long after the demand for increased energy requires the replacement of part of the liquid milk with foods of greater caloric value. Chemical analysis has shown that proteins, fat, carbohydrate and salts are to be found in milk, and nutritional studies have demonstrated that these constituents together with the contained vitamins are peculiarly valuable in promoting growth and in maintaining physiologic well being. In line with the current tendency to examine the possible nutritive value of both organic and inorganic constituents present in food materials in mere traces, milk has recently been studied anew by methods not ordinarily applied to food analysis. Thus, Blumberg and Rask,<sup>1</sup> using the spectrograph, studied the ash of nineteen samples of milk, the spectrum of the ash was photographed and the presence of the elements detected by searching for their "raies ultimes" on the spectrogram. In addition to the calcium, phosphorus, magnesium, potassium and sodium present in considerable concentrations, traces of barium, boron, copper, iron, lithium, rubidium, strontium, titanium and zinc were found. Again in subjecting the fatty acids of butter fat to examination for linoleic and

NUMBER 3

191

linoleic acids, Eckstein<sup>2</sup> has found a concentration of 0.21 and 0.12 per cent, respectively, for these compounds. If, as it appears, these fatty acids are "essential" in the nutritional sense, there is here another explanation for the unique food value of milk. There is thus slowly accumulating information on the finer details of the composition of milk, which in its fulfillment will doubtless explain much of the recognized excellence of this fluid from the point of view of nutrition. One commentator<sup>3</sup> has referred to this growing situation as the challenge of nutrition to the chemist.

A recent contribution deals with the cholesterol content of milk. Ansbacher and Supplee<sup>4</sup> were led to undertake this investigation because of the growing importance of the lipids, notably the sterols. It is well known that ergosterol, one of the sterols, is endowed with marked antirachitic properties when irradiated with ultraviolet energy and, as this sterol usually accompanies cholesterol in nature, the determination of the distribution of the latter lipid in milk might have considerable importance in elucidating the mechanism whereby both liquid and dried milk is rendered antirachitic by irradiation. As might be expected, the butter fat fraction of the milk contained the greatest concentration of sterol, about 0.3 per cent, however, it is significant that the butter fat did not contain all of the sterol in the milk. The skim milk, whey and casein all had sterol but the lactalbumin showed 0.18 per cent, more than half the concentration of the butter fat. It was observed that the sterol combined with the lactalbumin is more constant than that of the other milk constituents, indeed, the sterol of the whole milk seems to be independent of the fat content.

Previous studies have demonstrated that butter fat on irradiation with ultraviolet energy becomes active in curing rickets. Ansbacher and Supplee subjected a suspension of lactalbumin to similar irradiation and demonstrated that the sterol combined with this protein could be thus rendered antirachitic. These investigators are inclined to view the sterol component as the so-called prosthetic group of the protein, much as is nucleic acid in nucleoprotein and hematin in hemoglobin. The lipoprotein group has never been well defined, the sterol-lactalbumin combination is one of several recently described substances that are lending increased biochemical significance to this group of compound proteins.

A recent comparison<sup>5</sup> of several therapeutic agents on the basis of their efficacy in curing infantile rickets has indicated that, when judged on the number of rat units of vitamin D, irradiated milk was superior to milk from cows fed irradiated yeast, to cod liver oil and to viosterol. It appears that the effect of irradiating milk with ultraviolet energy is to produce a product

of peculiar efficacy in the treatment of human rickets. It is known that such treatment of ergosterol alone yields a series of products, one of which is vitamin D. The foregoing studies on the sterols in milk suggest that the combination of provitamin D with the milk proteins may enhance the usual effect of irradiation on this sterol.

#### EXPERIMENTAL ELEPHANTIASIS

The history of medicine shows that, whenever it has been possible to imitate experimentally the phenomena of human disease, the way has usually been paved for a better understanding of the malady and often a greatly improved facility of diagnosis, prognosis and treatment. Perhaps recent investigations will initiate some progress in present conceptions of lymphedema and elephantiasis. As far as the latter belongs to the acquired type, lymph stasis due to various etiologic agents has been assumed to play the most important part. The majority of the cases in the tropics, where elephantiasis occurs as an endemic disease, are due to filariasis caused by infestation with *Wuchereria bancrofti*. In temperate climates the same end results seem to follow a variety of experiences. Heretofore attempts to produce lymph stasis and permanent lymphedema in extremities has not been especially successful, presumably owing to the readiness with which somehow a restoration of lymph drainage occurs.

Investigations<sup>1</sup> at the Harvard School of Public Health in Boston seem to have been more fortunate. By successive cannulation of lymphatic trunks of the extremities of animals, followed by injections of crystalline silica and quinine hydrochloride, obstruction finally occurred. Lymphedema developed after such injections and eventually became pronounced. The protein content of the edema fluid rose slowly to above 4 per cent. With the establishment of lymphedema the subcutaneous connective tissue increased and the leg gradually became elephantiac. It is reported that, when the lymphatics are blocked in such experiments water and salts continue to pass in and out of blood capillaries but extravascular protein cannot move from the part except by diffusion of the tissue fluid through the tissue spaces. On first establishment of lymph block, these spaces are extremely small and diffusion through them is slow, but as the part enlarges the tissue spaces become quite noticeable even though there has been large new formation of fibrous tissue. Under these circumstances the tissue follows gravity rapidly. One of the first effects of lymphatic block is the appearance of varicose lymphatic trunks. These are seen as hugely dilated elements. When cannulated centrally lymph flows out of the cannula plentifully, indicating the incompetence of the valves. As blockage persists, lymph capillaries in the skin and subcutaneous

tissue dilate widely and their walls become somewhat thickened

According to the Harvard physiologists, overgrowth of connective tissue and dilatation and thickening of lymphatic capillaries begin to be noticeable when lymphedema has been present for two months. These changes are those underlying elephantiasis. It is well known that in the presence of chronic lymphatic obstruction the part involved becomes notably susceptible to infection. Drinker and his associates<sup>1</sup> aver that, whatever may be the effect of acute lymphatic block in restraining acute infection, there can be no doubt that when a part loses lymphatic drainage permanently, so that with each period of activity there is no movement of fluid from the tissues to the lymphatics out of the region, there develops a surprising susceptibility to streptococcal infection. Periods of repeated infection intensify the changes in the tissue fluid which result from lymphatic obstruction alone, and it is not surprising, Drinker adds, that they have been considered the underlying cause of elephantiasis. They are not the essential cause, but they do accelerate the new growth of connective tissue.

## Current Comment

### SUDDEN DEATH AFTER INJECTION OF HUMAN SERUM

While normal human serum is presumably the least toxic therapeutic agent that can be used in attempting passive immunization of children, the opinion that such serum can be injected without danger into children is not justified by clinical experience. European clinicians<sup>1</sup> report that the administration of human serum to children under 14 years of age is sometimes followed by severe or even serious serum disease in approximately 3 per cent of the cases. The term "auto-anaphylaxis" has been suggested as a descriptive title for this type of serum shock. The term "iso-anaphylaxis," recently suggested,<sup>2</sup> is, however, more nearly in accord with recent immunologic nomenclature. Assuming that the adult human serums are selected and prepared by competent clinicians and laboratory technicians so as to rule out all dangers from the selection of pathologic serums or from subsequent bacterial contamination, the most obvious explanation of iso-anaphylactic toxicity would be that it is due to physical or chemical denaturation of normal serum proteins. This is probably not the full explanation, however, for investigators<sup>3</sup> report equally serious serum disease following the injection of absolutely fresh, nonheated and demonstrably sterile normal human serum, to which antiseptic or chemical preservatives had not been added. A second obvious explanation would be to assume that the iso-allergic toxicity is due to circulating food proteins<sup>4</sup> or to other circulating

environmental allergins,<sup>5</sup> to which the children receiving the serum had a hereditary or acquired specific sensitivity. If this is so, one evident precaution would be to withdraw no serum from donors until at least eight hours had elapsed after the last protein meal. Less plausible explanations are based on the still hypothetical differences in tissue and serum specificity between young children and adults,<sup>7</sup> on the possibility of allergic shock due to the use of adult serums of an alien blood group and on the conceived possibility of "reversed anaphylaxis."<sup>8</sup> The latter would be due to the presence of specific or nonspecific "antibodies" in many normal adult circulations<sup>9</sup> against antigens conceivably present in certain children. Thus far, but one case of iso-allergic serum disease has been reported in American literature.<sup>10</sup> There are several still unreported cases, however, in the recent California experience. No fatality is as yet on record directly attributable to iso-anaphylactic shock.<sup>11</sup>

### FACTORS IN THE REGENERATION OF HEMOGLOBIN

For more than a decade it has been evident that iron is not always the only factor that needs to be supplied to the body in conditions that call for regeneration of the blood cells. Obviously the ferruginous blood pigment hemoglobin cannot be synthesized in the absence of available iron, which is one of its component elements. It has been established since 1920 that liver contains abundant material, still undetermined in character, that can be converted by anemic animals into hemoglobin and red blood cells. One might well expect, therefore, that in protracted anemia, such as can be produced by repeated hemorrhage, the rich store of hemoglobin production factors in the liver of the affected individual would be greatly diminished. The recent studies of Whipple and Robschert-Robbins<sup>1</sup> at the University of Rochester School of Medicine and Dentistry afford the surprising information that such depletion is by no means a regular occurrence. Thus it was noted that anemic horse liver contains no less of the hemoglobin production factors than do the normal controls. Evidently the normal liver guards its reserve of hemoglobin production factors with the utmost care, and repletion must be prompt and effective. In human cases of pernicious anemia and aplastic anemia, Whipple and Robschert-Robbins have reported a surplus accumulation of these hemoglobin producing factors in the liver, due possibly to the lack of outlet for this material, as the body cannot fabricate red cells due to a deficiency factor (pernicious anemia) or to lack of red marrow (aplastic anemia). Only in severe liver disease with signs of failure of liver func-

tion did they find a significant fall in the concentration of hemoglobin production factors in the human liver. This does not mean that the store of iron is not depleted in the anemic individuals. Whipple and Robschert-Robbins venture to argue that the liver is busy with the manufacture of parent hemoglobin building material and that during moderately severe anemia caused by loss of blood this mechanism is accelerated and no depletion of reserve is permitted in spite of a severe drain from loss of hemoglobin by bleeding. In fact, if one considers the observation that the iron content is much decreased in these anemic livers and that iron has a definite influence on hemoglobin regeneration, they add, one may properly hold that the anemic liver actually contains more of the organic factors that promote hemoglobin regeneration than does the non-anemic control liver. One therefore may be driven to the admission that the liver in moderate anemia (compared with controls) does contain much less iron and therefore more organic factors that promote hemoglobin regeneration.

## Association News

### THE ATLANTIC CITY SESSION

Eighty-Sixth Annual Session to Be Held in June

The Eighty-Sixth Annual Session of the American Medical Association will be held in Atlantic City N. J., June 10 to 14, 1935.

### MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, Central daylight saving time. The speaker will be Dr. W. W. Bauer. The next three broadcasts will be as follows:

July 26	The First Month
August 2	Dog Days
August 9	Death Angel

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

### ALABAMA

**Personal**—Dr. Charles A. Mohr, Mobile, resigned as health officer of Mobile County, effective July 1.—Dr. Charles A. Thigpen, Montgomery, recently received the honorary degree of doctor of laws from the University of Alabama.—Dr. Robert L. Allen has assumed his duties as medical officer in charge of the marine hospital at Mobile, succeeding Dr. William S. Bean Jr.

### ARKANSAS

**Society News**—The Ouachita County Medical Society was recently addressed in Camden by Drs. Henry F. DeWolf on "Lymphogranuloma Inguinale", Ernest H. White, "Pituitrin in Obstetrics" and Daniel R. Hardeman, Little Rock, "Some Phases of Intravenous Medication".—At a meeting of the Madison County Medical Society in Huntsville, June 5, speakers were Drs. William R. Brooksher, Fort Smith, value of the roentgen ray to the general practitioner, Sidney J. Wolfertmann, Fort Smith, bedside diagnosis of diseases of the upper abdomen, and Frank N. Gordon, Fayetteville, policies of the

veterans' administration.—The Tri-County Clinical Society was addressed in Hope, recently, by Dr. William S. Kerlin on "Angina Pectoris", Forno M. Talbot, D.D.S., "Dietary Deficiencies as Related to Dental Diseases," and Dr. Douglas L. Kerlin, Shreveport, treatment of the psychoneuroses.—Speakers before the Ninth Councilor District Medical Society at Eureka Springs, June 5, included Drs. Milton C. John, Stuttgart, on "Office Treatment of Hemorrhoids", Ira F. Jones, Fort Smith, "Intestinal Obstruction," and Fergus O. Mahony, El Dorado, "The Practitioner of Medicine in this Changing World."

### CALIFORNIA

**Department of Legal Medicine Created**—The College of Medical Evangelists, Los Angeles, has recently created a department of cultural and legal medicine. Dr. Percy Tilson Magan, professor of public health, has been appointed to head the new department.

**Changes at Stanford**—Stanford University School of Medicine, San Francisco, announces the following changes on its faculty, effective September 1:

Dr. Frank H. Rodin promoted to assistant clinical professor of surgery (ophthalmology).

Dr. Alfred Baker Spalding emeritus professor of obstetrics and gynecology.

Dr. Dohrmann Kaspar Pischel associate clinical professor of surgery (ophthalmology).

**Committee to Study Health Insurance**—At the recent annual convention of the California Medical Association, a committee was appointed to make a survey of health insurance. Members are Drs. Alson R. Kilgore and Rodney A. Yoell, San Francisco, Robert A. Peers, president-elect of the California Medical Association, William R. Molony, Los Angeles, president of the state board of medical examiners, and Harry H. Wilson, Los Angeles, secretary, Los Angeles County Medical Society. Dr. Peers, who is going abroad soon, is expected to study health insurance in Europe.

**Death from Rabies**—The first death from rabies in a human being in California in two years occurred in April in a child 3 years of age. Bitten on the right cheek by a stray dog, March 30, the child was taken at once to a clinic. Antirabic treatment was started within three hours after the child had been bitten and twenty-one doses were administered. On the twenty-second day, one day after the treatment had been completed symptoms of rabies developed. The child died on the third day. The diagnosis was confirmed by finding characteristic intracellular Negri bodies in the brain. Other children were bitten by this dog, which was located and placed under observation. It died four days later.

### CONNECTICUT

**Personal**—Dr. Samuel C. Harvey, professor of surgery, Yale University School of Medicine, has been elected president of the Association of the Yale Alumni in Medicine.—Dr. Harvey Cushing, New Haven, was awarded an honorary degree by Syracuse University, Syracuse, N. Y., June 4.

**Public Health Meeting**—The Connecticut Public Health Association held its annual meeting at the Laurel Heights State Tuberculosis Sanatorium, Shelton, June 27, under the presidency of Dr. John L. Rice, now health officer of New York. Dr. Edward J. Lynch, superintendent of the sanatorium, gave the address of welcome.

**Dr. Greenburg Named Acting Health Officer**—Dr. Leonard Greenburg, assistant clinical professor of public health at Yale University School of Medicine, has been appointed acting health officer of New Haven. Dr. Greenburg succeeds Dr. Herbert R. Edwards who is now directing the tuberculosis program in New York City under Health Commissioner John L. Rice, formerly health officer of New Haven. In 1923 Dr. Greenburg received the degree of doctor of philosophy from Yale University and in 1930 the degree of doctor of medicine. He was a member of the U. S. Public Health Service from 1918 to 1932.

### DISTRICT OF COLUMBIA

**Society News**—Dr. Elizabeth A. Kittredge was elected president of the Women's Medical Society of the District of Columbia at its recent annual meeting. Dr. Edith Scville Coale read a paper on "Undulant Fever".—Dr. Sterling Ruffin was recently elected president of the Washington Heart Society and Dr. James W. Esler, secretary.

**Personal**—Georgetown University conferred the honorary degree of doctor of laws on Major Edgar Erskine Hume at its annual commencement June 11. Dr. Hume is librarian of the Army Medical Library.—Alice C. Evans, bacteriologist

of the U S Public Health Service, received the honorary degree in medicine from the Woman's Medical College of Pennsylvania, Philadelphia, June 6 —Dr James P Leake, senior surgeon, U S Public Health Service, has been relieved from duty in the division of sanitary reports and statistics and assigned to duty in the division of scientific research, effective June 23

**Health at Washington**—Telegraphic reports to the U S Department of Commerce from eighty-six cities, with a total population of 37 million, for the week ended July 7, indicate that the highest mortality rate (188) appears for Washington and for the group of cities as a whole, 108. The mortality rate for Washington for the corresponding period last year was 145, and for the group of cities, 96. The annual rate for eighty-six cities for the twenty-seven weeks of 1934 was 12 as against a rate of 115 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

### ILLINOIS

**Society News**—Speakers before the Whiteside County Medical Society in Prophetstown, June 26, were Drs Walter H Nadler and Merritt Paul Starr, Chicago, on diabetes and control of edema in congestive heart failure by diuresis, respectively.

#### Chicago

**Society News**—Dr Charles H Phifer was installed as president of the Chicago Medical Society at its recent annual election, and Dr Julius H Hess was named president elect —Dr Edward L Cornell was named president elect of the Chicago Gynecological Society, June 22, and Dr Irving F Stein was installed as president. Dr Charles Edwin Galloway is secretary.

**University News**—Dr Harry L Huber has been promoted to associate clinical professor of medicine, Division of Biological Sciences, University of Chicago, effective July 1. Dr Rudolph Schindler, Munich, has been appointed visiting professor of medicine in the division—Dr Albert E Luckhardt was recently appointed associate clinical professor in the department of medicine at Loyola University School of Medicine.

### INDIANA

**Personal**—Dr Charles P Emerson, formerly dean Indiana University School of Medicine, was awarded the honorary degree of doctor of science by Amherst College, Amherst, Mass., his alma mater —Dr Leslie M Jones has been appointed superintendent of Epworth Hospital, South Bend effective June 11.

**University News**—A collection of thirteen medical works written from seventy-five to a hundred years ago, has been contributed to the Indiana University Medical Center Library by Dr Stephen B Sims, Frankfort —The departments of occupational and physical therapy at the Indiana University Medical Center, Indianapolis were recently consolidated to promote efficiency and economy.

**Outbreak of Typhoid**—Eleven cases of typhoid were reported in an outbreak in New Bethel, June 20. Eight of the eleven persons attended a public dinner in the town, May 8. Dr Oscar D Ludwig, health commissioner of Marion County, was of the opinion that a carrier was responsible, although at the time of his report a definite source for the outbreak had not been determined. New Bethel has a population of about 350.

### IOWA

**Personal**—Dr John H Peck, Des Moines, has resigned as president of the Iowa Tuberculosis Association because of his increasing work as medical director of the organization. T P Eslick, attorney, was elected president for the interim until the annual meeting of the association in Cedar Rapids in September —Dr Frank Harold Reuling, Waterloo, received the merit award of Northwestern University Alumni Association on 'illumination night' in Evanston, Ill., preceding the commencement exercises June 15. The award is given annually to alumni for 'worthy achievement which has reflected credit upon their alma mater.'

**Twin Lakes Assembly**—A dry diagnostic clinic constituted the program of the twelfth annual assembly of the Twin Lakes District Medical Society at Burns' Alhambra Pavilion, Twin Lakes, Rockwell City, June 21. A talking motion picture on 'Forceps Delivery' made by Dr Joseph B De Lee, Chi-

cago, opened the program. Dr Edward Starr Judd, Rochester, Minn., conducted a clinic in general surgery, Dr Karl A Menninger, Topeka, Kan., neuropsychiatry, Dr Adolph Sachs Omaha, heart disease, and Dr Henry F Helmholtz, Rochester, Minn., pediatrics. An address was delivered by Dr Edward H Skinner, Kansas City, on "Collective Individualism versus Regimentation in Medical Practice." Dr William M Shipley, Ottosen, was elected president at this session, and Dr Paul W Van Metre, Rockwell City, reelected secretary. The Twin Lakes District Medical Society is composed of the medical societies of Calhoun, Carroll, Greene, Hamilton, Humboldt, Ida, Sac, Kossuth, Pocahontas, Webster and Wright counties.

**Society Conducts Laboratory Course**—The speakers' bureau of the Iowa State Medical Society is conducting a laboratory course in Des Moines, July 16-28. Round table discussions are led by the following physicians:

Clarence W Baldrige Iowa City and Frederick H Lamb Davenport Hematology  
Julius P Weingart Des Moines and Milford E Barnes Iowa City Immunology  
Daniel J and Mrs Glomset Des Moines Blood Chemistry  
John L Kestel Waterloo Urinalysis  
Irving H Boris Iowa City Bacteriology  
John T Strawn Des Moines Gastric Analysis and Stool Analysis  
Frank P McNamara Dubuque Tissue Examination  
Herbert W Rathe Waverly Metabolism  
Benjamin F Wolverton Cedar Rapids Electrocardiography  
Harold Dabney Kerr Iowa City and Thomas A Burcham Des Moines Roentgen Rays

Laboratory demonstrations in these subjects are also a part of the course.

### MICHIGAN

**Society News**—Dr John E Gordon gave a paper before the Muskegon County Medical Society in Muskegon, June 22, on "Comparison of American and European Practice in Control of Communicable Diseases." —At a meeting of the Saginaw County Medical Society, June 19, Dr William S O'Donnell, Detroit, spoke on nephritis in children —Dr Hans von Hattingberg, professor of psychotherapy, Berlin University, addressed the Detroit Society of Neurology and Psychiatry, June 28, on "The Psychotherapeutic Movement."

**Faculty Changes at State University**—Announcement is made of the following promotions on the faculty of the University of Michigan Medical School, Ann Arbor, effective July 1:

Dr John Morris Dorsey associate professor of psychiatry  
Dr Cameron Hight assistant professor of surgery  
Dr Harold William Jacox assistant professor of roentgenology  
Dr Vincent C Johnson assistant professor of roentgenology  
Dr Edgar A Kahn associate professor of surgery  
Dr Konstantin Lowenberg assistant professor of neuropathology in psychiatry  
Dr Eugene Breckenridge Potter associate professor of surgery

### MINNESOTA

**Personal**—Dr Edward C Rosenow, Rochester, received the honorary degree of doctor of science from Carleton College, Northfield, June 11, and Dr Donald C Balfour, Rochester, the degree of doctor of laws —Dr Robert B J Schoch has been appointed city health commissioner of St Paul, he was chief deputy coroner of Ramsey County from August 1919 until he resigned in 1926 —Dr Charles W Moore, Eveleth, was recently the guest of honor at a testimonial dinner given by professional and business friends —Dr Charles H Mayo, Rochester, Minn., received the merit award of the North western University Alumni Association on 'illumination night' in Evanston, Ill., preceding the commencement exercises, June 15. The award is given annually to alumni for 'worthy achievement which has reflected credit upon their alma mater.'

### MISSISSIPPI

**Personal**—Dr Hugh L McKinnon has been appointed superintendent of the Mississippi School and Colony for Feeble minded, Ellisville, succeeding Dr Hubert H Ramsay —Dr Russell R Welch, assistant superintendent of the state insane hospital at Jackson, has been named superintendent of East Mississippi Hospital, Meridian, succeeding Dr Matthew J L Hoyer.

**County Societies Merge**—The consolidation of the Clarksdale and Six Counties Medical Society and the Delta Medical Society culminated in a meeting in Clarksdale recently. The combined group will be known as the Delta Medical Society. Dr Leon H Brevard Dundee, was named president to take office January 1. Until that time Dr Richard C Smith, Drew, outgoing president of the old Delta Medical Society, will serve. Dr Frank M Acree Jr, Greenville, is the secretary. Representative committees of the two societies approved this merger in December at which time the Clarksdale group

had already voted for the union. However, no further action was taken until the recent meeting of the Delta society. Three meetings a year will be held at Clarksdale, Greenville and Greenwood in rotation.

### MISSOURI

**Personal**—Dr John W. Vaughan recently completed fifty years in the practice of medicine, all of which have been spent in St. Louis—Dr David P. Barr, St. Louis, sailed for Melbourne, Australia, June 16, where he will give a course of lectures on diseases of the endocrine glands at the University of Melbourne—Dr Bransford Lewis, St. Louis, was presented with a bronze plaque at the annual banquet of the American Urological Association in session at Atlantic City in recognition of his services in editing "The History of Urology"—Dr Hugo Ehrenfest was recently promoted to professor of clinical obstetrics and gynecology at Washington University School of Medicine, St. Louis.

### NEBRASKA

**Society News**—The obstetric department of the University of Nebraska College of Medicine has created an Oliver Wendell Holmes trophy to be awarded annually to the counselor district showing the best record in obstetric mortality—Speakers at a meeting of the Sixth Council District Medical Society, David City, June 7, were Drs Edwin Davis, on "Prostatic Obstruction", Rodney W. Bliss, Omaha, The Kidney in Prostatic Obstruction," and Warren Thompson, Omaha, "The Heart in Prostatic Hypertrophy."

### NEW MEXICO

**Personal**—It is reported that Dr Frank S. Fellows of the U. S. Public Health Service, who is now medical director of the Indian Bureau in Alaska, has been transferred to the southwest with headquarters in Albuquerque, to succeed Dr Langdon R. White, who has been transferred to the territory surrounding Minneapolis. The southwest territory includes Arizona, New Mexico and southern Colorado.

**Measles Epidemic at Jemez**—Twenty children died in an epidemic of measles, which began about June 1 in the Indian pueblo of Jemez and had attacked 130 of the 147 children in the pueblo by June 28, according to newspaper reports. A temporary hospital was set up by physicians and nurses of the Indian Medical Service but some of the parents refused to allow their children to be taken to the hospital. It was said that none of those who were properly cared for died. The population of the pueblo is about 650.

### NEW YORK

**State Stops Distribution of Toxin-Antitoxin**—The division of laboratories and research of the state department of health has discontinued distribution of diphtheria toxin-antitoxin and will hereafter provide only toxoid. Distribution of toxoid was begun two years ago, but toxin-antitoxin has been supplied on request. Accumulated experience is considered to have demonstrated the superiority of toxoid and requests for the older material have diminished so that its preparation is no longer warranted, the department announces. Immunity is more speedily acquired with toxoid and the percentage of persons immunized is greater and in addition it does not contain horse serum, to which many persons are hypersensitive.

**Dr Davenport Retires**—Charles B. Davenport, Ph.D., for thirty years director of the Station for Experimental Evolution of the Carnegie Institution, Cold Spring Harbor, has announced his retirement. Albert T. Blakeslee, Ph.D., assistant director has been appointed his temporary successor. Dr Davenport served as associate professor of zoology at the University of Chicago until his appointment to the Carnegie post in 1904. In 1910 he became director also of the Eugenics Record Office at Cold Spring Harbor. Dr Davenport has served as president of the American Society of Zoologists, the Eugenics Research Association, the Galton Society and the International Federation of Eugenics Organizations and as vice president of the American Association for the Advancement of Science, the American Society of Naturalists and the National Institute of Social Sciences. He will continue his research privately with headquarters at the Eugenics Record Office according to the New York Times.

### New York City

**Scarlet Fever Isolation Period Reduced**—Uncomplicated cases of scarlet fever may now be released from isolation after twenty-one days as a result of an order recently issued by the health department. A trial of the twenty-one day isolation period was inaugurated in Brooklyn in 1932,

while in other boroughs uncomplicated cases were held till the thirtieth day. Study of the results of this test showed that the number of secondary cases from the reduction was so small that this disadvantage was outweighed by the advantages of shorter isolation. Complicated cases will be subject to the same regulations as before.

**Advisory Obstetric Council Appointed**—Dr John L. Rice, commissioner of health, has appointed a council of obstetricians and gynecologists to make a complete study of the maternal and infant mortality situation in the city. The new council will study institutional obstetrics, including a survey of facilities for maternity cases, with special reference to environment, equipment and adherence to accepted hospital standards, organization and control of hospital staffs, proprietary hospitals and nursing homes, prenatal care services throughout the city, the status, control and teaching of midwives, and the value of confinement at home and its limitations and methods for instruction of the public in adequate maternity care. Dr Rice is chairman of the council, Dr Alfred E. Shipley vice chairman and Dr George W. Kosmak secretary. Members are the following physicians:

Donald E. Law	Daniel V. Catalano	John H. Telfair
Benjamin P. Wat on	Joshua Ronsheim	Arthur C. Butts
George Gray Ward	Alfred C. Beck	Harry P. Mencken
Henricus J. Stander	O. Paul Humpstone	George J. J. Lawrence
Frederick C. Holden	Harvey B. Matthews	John P. C. McManus
Charles A. Gordon	Harry Aranow	

**Vacancy in Health Department**—The Municipal Civil Service Commission of New York invites applications for the position of director of district health administration until 4 p. m., August 2. Application blanks will be mailed on request, provided 3 cents in postage stamps accompanies the request. Applicants who are summoned for the examination will be required to pay a fee of \$6.50 before taking the first assembled test. The examination is open to all citizens of the United States more than 21 years old and the requirement that every application must bear certificates from four persons living in New York is waived for persons living outside the state, who must, however, present such certificates from persons engaged in business or resident elsewhere. Candidates will be graded on their experience, a written test on the duties of the position and an oral test. Those who receive a passing mark in experience will be summoned for the duties test, which will be held only in New York. Candidates must be graduates from approved medical schools and must possess licenses to practice medicine. They must have had at least six years of medical experience, three years of which shall have been in responsible positions concerned with public health administration. At the time of the written test each candidate must present his license, and those who live outside New York must have their licenses endorsed by the board of regents of the University of the State of New York before their names can be certified for appointment. The position includes administrative charge and executive supervision of district health center administration, direction of activities of medical inspectors and other employees, lecturing and writing concerning activities of the department, contact with department officials, the public and cooperating agencies and keeping of records of the division. The salary is \$6,500 a year.

### NORTH CAROLINA

**Society News**—Among the speakers at the spring meeting of the Tenth District Medical Society in Marion May 16, were Drs Frederic M. Hanes, Durham, on "Intra-cranial Hemorrhages" and Fred E. Motley, Charlotte, on sinusitis.

### OHIO

**Appointments to Medical Board**—Dr John H. J. Upham, Columbus, chairman board of trustees, American Medical Association, was recently reappointed a member of the State Medical Board of Ohio for the fourth time. Dr Louis T. Franklin Chillicothe was appointed to succeed Dr John Stewart Hagen Cincinnati.

**Society News**—Speakers at a meeting of the Adams County Medical Society in Batavia, June 20, were Drs Parke G. Smith Cincinnati on "Anatomy of the Prostate Mechanism of Prostate Obstruction and Present Status of Prostatic Surgery," Otto J. Seibert, Cincinnati, "Cancer of the Breast" and Carl Minning Williamsburg, "Gonorrhea in the Male"—Dr Cecil Striker Cincinnati, addressed the Darke County Medical Society, Greenville May 18 on treatment of diabetes—Dr Clement L. Jones Springfield addressed the Miami and Shelby County Medical Societies June 7 in Sidney on angina pectoris—Dr James R. Tillotson Lima, discussed

fractures at a meeting of the Hardin County Medical Society, Kenton, May 17—Dr Charles L. Brown, Ann Arbor, Mich., addressed the Mahoning County Medical Society, Youngstown, June 19, on "Diagnostic Survey and Medical Management of Chronic Gallbladder Disease"—Dr John H. J. Upham, Columbus, addressed the Stark County Medical Society, Alliance, in May, on "Modern Aspects of Heart Disease in Middle Age"—Dr Harold K. Shawan, Detroit, addressed the Marion Academy of Medicine, Marion, June 5, on "Cranio-cerebral Injuries" and "Surgical Management of the Toxic Goiter Case"

### OKLAHOMA

**University News**—Dr Rufus Quitman Goodwin was recently promoted to assistant professor of medicine at the University of Oklahoma School of Medicine, Oklahoma City, Dr Raymond Lester Murdock to associate professor of surgery, and Dr Herbert Dale Collins to assistant professor of surgery

### OREGON

**Society News**—Speakers at the annual meeting of the Southern Oregon Medical Society in Medford, May 8, included Drs George W. Swift, Seattle, on "Treatment of Head Injuries", Ralph A. Fenton, Portland, "Early Diagnosis of Middle Ear and Mastoid Disease", and Albert H. Ross, Eugene, "Protein and Edema"—Dr George I. Hurley, Eugene, addressed the Lane County Medical Society, Eugene, May 17, on "Medical Economics and State Medicine"—Drs Warren B. Penney, Tacoma, Wash., and Thomas M. Joyce, Portland, addressed the Central Willamette Medical Society, Eugene, May 3, on "Cardiac Arrhythmias" and "Treatment of Goiter", respectively—Dr Charles E. Hunt, Eugene, presented a paper before the Portland Society of Obstetricians and Gynecologists, May 23, on "Recent Trends in Obstetric Analgesia"—Dr James E. Campbell, Sutherlin, has been appointed health officer of Douglas County, succeeding Dr Bertram R. Shoemaker, Roseburg

### PENNSYLVANIA

**Fifty Years in Practice**—Dr Alice Rogers Easby, Media, and Dr Florence May Sibley Lee, Haverford, received gold medals at the annual commencement of the Woman's Medical College of Pennsylvania, June 5, in celebration of fifty years of medical practice. They were members of the class of 1884

**Personal**—Dr William L. Estes Sr, Bethlehem, received the honorary degree of doctor of science at the annual commencement of Lehigh University, June 12. Dr Estes lectured on physiology and hygiene at Lehigh from 1883 to 1923—Dr William B. Fulton, Pittsburgh, has succeeded Dr Elizabeth B. Bricker, Lutz, as head of the industrial hygiene and sanitation section of the state department of labor and industry, Harrisburg—Dr Henry F. Ulrich has been appointed coroner of Snyder County to succeed the late Dr A. Jerome Hermann, Middleburg

### VIRGINIA

**Personal**—Dr Lawrence T. Price has resigned as professor of clinical genito-urinary surgery at the Medical College of Virginia, Richmond—Dr Albert Eugene Casey of the Rockefeller Institute for Medical Research, New York, has been appointed associate professor of pathology at the University of Virginia School of Medicine

**Society News**—At the quarterly meeting of the Southside Virginia Medical Association in Suffolk, June 12, speakers included Drs Martillus H. Todd, Norfolk, on "Abdominal Emergencies", Thomas Dewey Davis, Richmond, "Diagnosis of Chronic Appendicitis", and Philip Jacobson, Petersburg, "Surgery of the Normal Thyroid"—The Bedford County Medical Society was recently reorganized with Dr Charles H. Bondurant, Bedford, president, and Dr Joseph A. Rucker, Bedford, secretary. At the first meeting speakers were Drs Samuel Beverly Cary, Roanoke on "Transurethral Resection", Collins D. Nofsinger, Roanoke, "Diabetes", and Eddie L. Johnson, Bedford, "History of Medicine During the Past 125 Years"—Drs James M. Hutcheson and Wilbur R. Bracey, Richmond, among others, addressed the Mecklenburg County Medical Society, Clarksville, May 8 on "Cardiac Therapy" and "Cancer of the Lung", respectively—Dr Carrington Williams, Richmond, addressed the Lynchburg Academy of Medicine, May 7, on "Lesions of the Stomach"—Dr Wyndham B. Blanton, Richmond, among other speakers, led a discussion of medical economics at a meeting of the Post-Graduate Medical Society of Southern Virginia Farmville May 15

### WISCONSIN

**Society News**—At the tenth annual meeting of the Seventh District Medical Society in Whitehall, May 16, speakers were Drs Elmer L. Sevringhaus, Madison, on "Glandular Therapy", Fred R. Thompson, Rochester, Minn., "Present-Day Management of Prostatic Obstruction", Thomas J. O'Leary, Superior, "Surgery of the Gallbladder", and Joseph G. Mayo, Rochester, "Secondary Anemias". Mr J. George Crownhart, executive secretary, State Medical Society of Wisconsin, also made an address on medical economics—Dr Lawrence V. Littig, Madison was elected chairman of the radiology section of the State Medical Society of Wisconsin at the annual meeting in Janesville in May—Drs Fremont A. Chandler, Chicago, and Joseph W. Gale, Madison, among others, addressed the Ninth Councilor District Medical Society at Stevens Point, May 10, on "Back Injuries, with Special Relation to the Lumbosacral Region" and "Surgical Treatment of Pulmonary Tuberculosis", respectively

### GENERAL

**Dr Kracke Awarded Medal**—Dr Roy R. Kracke, associate professor of bacteriology and pathology, Emory University School of Medicine, Emory University, was awarded the Ward-Burdick Medal of the American Society of Clinical Pathologists at its meeting in Cleveland, June 7-11, for his work on agranulocytic angina. Dr Frederick H. Lamb, Davenport, was installed as president. Dr Foster M. Johns, New Orleans, was named president elect, Dr Benjamin S. Kline, Cleveland, vice president, and Dr Alfred S. Giordano, South Bend, Ind., reelected secretary.

**Another Kind of Impostor**—Dr Fred Baker, Point Loma, Calif., recently reported that a young man using the name Walter J. Sherman had approached him asking for money to tide him over the difficulties incident to an automobile mishap. He claimed that he had just graduated from Cornell University Medical School, New York, and was on his way to take his internship in a Seattle hospital when he ran into a sheriff, who arrested him and confiscated his money for bail. He claimed to be a grandson of Mr Walter J. Sherman, Toledo, Ohio, and wore a Delta Kappa Epsilon pin. Mr Sherman in a report to Cornell University Medical College states that he has no Sherman grandsons and that this young man is a fraud.

**Regulations on Tuberculosis Eradication**—New regulations have been approved by the secretary of agriculture to govern the emergency animal disease eradication program. The first allotment of funds, totaling \$2,000,000, will be used for cattle tuberculosis work alone and will be spread over twenty-five states. The new regulations differ from those used in the regular conduct of the work principally in allowing states to participate in eradication work whether or not they expend any of their own funds for indemnities or for the cost of testing. Payments for cattle found to be tuberculous will be made on the basis of a maximum of \$20 a head of federal money for grade cattle and \$50 for registered pure bred cattle.

**International Congress of Veterinarians**—The twelfth International Veterinary Congress will be held in New York at the Waldorf-Astoria, August 13-18, under the presidency of Prof. E. Leclanche, Paris. Among subjects listed on the program of interest to physicians are research on filtrable viruses, research on contagious abortion, eradication, immunity and protective inoculation against tuberculosis, psittacosis, pasteurization of milk, and unification of methods of meat inspection. Among speakers listed are Dr Gaston Ramon, assistant director, Pasteur Institute, Paris, Prof. O. Bang, Copenhagen, Denmark, Dr Charles Guerin, Paris, Prof. G. Forsell, Stockholm, Sweden, Karl F. Meyer, Ph.D., San Francisco, and John R. Mohler, chief, bureau of animal industry, U. S. Department of Agriculture. This is the first congress of its kind to be held outside of Europe. Physicians are eligible to extraordinary membership, the cost of which is \$5 and which includes the complete proceedings.

**Impostor in Texas**—A physician of Midland, Texas, reports that a man claiming to be a Philadelphia physician borrowed money on the strength of a hard luck story and omitted returning it. The man was traveling in a Packard car, with a woman, a little girl and a boy. He said that he had lost his billfold and that he would return the money as soon as he reached El Paso, where he was known. He gave a card on which was printed "Hedrik Von Tromp, M.D., Phone Penn 6780, Physician and Surgeon, 1712 Chester Ave., Philadelphia, Pa." He also wrote on the card his license number, Pennsylvania 51931, and stated that he had practiced in Philadelphia since 1900. When the money was not returned the next day as promised, the Texas physician investigated

and found that a 1916 directory of Philadelphia did not give his name. Records of the American Medical Association do not contain such a name and the Philadelphia County Medical Society reported that the name was unknown there.

**News of Epidemics**—Thirty-six cases of typhoid, with one death, were recently reported in an outbreak at the village of Auburn, Ky. Four cases in Brooklyn have been traced to the eating of raw clams dug at Canarsie Beach in violation of health department warnings; there have been forty-five cases in New York since April 1. Clams were also suspected as the source of seven cases in Newport, Va., reported June 15. In Lebanon, N. H., four cases were traced to the use of polluted spring or well water, June 8. Sporadic cases were also reported in Toledo, Ohio, and Albuquerque, N. M. —Two cases of Rocky Mountain spotted fever were recently identified in Mecklenburg County, N. C. The belief was expressed that the disease was transmitted by ticks on a mule lent to a family by relief agencies. One child died after an illness of four days. —The Wisconsin state board of health reported that 8,167 more cases of measles occurred in the state in May than in May 1933.

**Society News**—Dr Louis A. Buie, Rochester, Minn., was elected president of the American Proctologic Society at its recent annual meeting, and Dr Frank G. Runyon, Reading, Pa., reelected secretary. The next annual session will be held in Atlantic City. —Dr Henry H. Forbes, New York, was elected president of the American Bronchoscopic Society at its annual session, June 11, and Dr Lyman G. Richards, Boston, reelected secretary. —At the annual meeting of the American Academy of Pediatrics, June 11, Dr Thomas B. Cooley, Detroit, was installed as president. Dr Henry Dietrich, Los Angeles, named president-elect, and Dr Clifford G. Grulee, Evanston, Ill., reelected secretary. —Dr Edward W. Archibald, Montreal, was elected president of the American Surgical Association, June 4-6, and Dr Vernon C. David, Chicago, reelected secretary. The next annual session will be held in Boston. —Dr Sara Josephine Baker, New York, was chosen president-elect of the Medical Women's National Association at the annual meeting in Cleveland. Dr Lena K. Sadler, Chicago, was installed as president and Dr Alice I. Conklin, Chicago, was made secretary.

### PHILIPPINE ISLANDS

**Society News**—At a recent meeting of the Manila Medical Society, speakers were Drs Candido M. Africa and Eusebio Y. Garcia, on "Parasitology of Schistosomiasis Japonica"; Jose Albert and Moises B. Abad, "Leukemoid Blood Picture in Acute Infectious Diseases"; Drs Albert and Julian L. Paguyo reported a case of agranulocytosis. —Dr Jose O. Nolasco reported a case of cardiac aneurysm and Dr Casimiro B. Lara presented excerpts from the annual report of the Culion Leper Colony at a recent meeting of the Culion Medical Society.

### FOREIGN

**Centenary of Medical School**—The University of Liverpool celebrated the hundredth anniversary of the founding of its medical school, May 11. Honorary degrees were conferred on the following, among others: Sir Thomas Lewis, Mr Wilfred B. L. Trotter, Mrs May Mellanby, London, Dr Henry R. Dean, Cambridge, and Prof. William Blair-Bell. Professor Blair-Bell held the chair of obstetrics and gynecology in the university from 1921 to 1931.

**British Medical Association**—The one hundred and second annual meeting of the British Medical Association will convene in Bournemouth, July 24-28, under the presidency of Dr Thomas G. Moorhead, regius professor of physic, Trinity College, Dublin. The annual representative meeting will begin at the Grand Hall, Town Hall, July 20 to continue on the following three week days. Prof. Vernon H. Mottram will give the popular lecture at the Grand Hall, Municipal College, July 27, on "Foods, Fads and Fashions." A feature of the meeting will be an exhibition of pictorial art of the medical profession at the Russell-Cotes Art Gallery. Dr S. Watson Smith, London, will be installed as president at this meeting.

**Society News**—The International Society of Geographic Pathology will hold a congress in Utrecht, July 26-28, subjects for discussion are cirrhosis of the liver, arteriosclerosis and organization of the society which was founded in 1927. —The fourth session of the International Office of Documentation for Military Medicine was held in Liege, June 28-30. Medical aspects of aviation, organization of the sanitary service at the base, international registration of wounds and diseases, immunization against infection of wounds, bacteriologic warfare, processes of disinfection, disimpregnation of the

linen and clothing of the gassed and interchange of sanitary formations during a campaign were among the subjects discussed.

**University News**—The University of Birmingham will open a department of industrial hygiene and medicine in October to undertake research in the application of medicine to industry and to offer special training to physicians now connected with industry or wishing to apply for such positions. —A gift of £15,000 has been made by Mr S. A. Courtauld to the Middlesex Hospital to found a clinical research unit, to be under the direction of the council of Middlesex Hospital Medical School and for the intensive and exclusive investigation of such diseases as may be selected from time to time. The *British Medical Journal* reports that "it is without precedent in this country for a medical school to be given direct access to and a large measure of control over, beds in the associated hospital."

**Cancer Research at Hebrew University**—A fund of about \$200,000 has been created by anonymous donors to establish and maintain a department at the Hebrew University, Jerusalem, for cancer research. Study will be directed first toward radiobiology, physiologic chemistry and the study of cells and tissues. At a recent meeting of the American members of the board of governors of the institution in New York, it was voted to nominate Dr Ludwig Halberstaedter, formerly of the staff of the Cancer Institute of Berlin, now with the Rothschild Hadassah Hospital in Jerusalem, as head of the department of radiobiology, Dr Georg Goldhaber, formerly Dr Halberstaedter's assistant, as his assistant in the new department, Dr H. A. Krebs, formerly of Berlin and now at Cambridge University, England, as head of the department of physiologic chemistry, and Dr Leonid Doljansky, formerly of the Institute of Pathology, University of Berlin, and now at the University of Copenhagen, as head of the new department to be devoted to tissue culture research and morbid anatomy.

### Deaths in Other Countries

Dr Carlos Heuser, Buenos Aires, author of many articles on radiography and gynecology, collaborator of *La semana medica*, died, March 28. Dr Heuser was the guest of the Radiological Society of North America at its 1931 meeting in St. Louis and received the society's gold medal in recognition of his work in methods of making roentgenograms for the study of pregnancy (*THE JOURNAL*, Dec. 19, 1931).

## Government Services

### Wellcome Medal and Prize

Competition for the Henry S. Wellcome Medal and Prize, consisting of a gold medal and a cash prize of \$500, is open for the best paper on "The Civilian Doctor's Part in a National Military Emergency." Competition is open to all medical department officers, former officers, acting assistant and contract surgeons of the army, navy, public health service, organized militia veterans' administration, U. S. Volunteers and the reserves of the United States, commissioned medical officers of foreign military services, and all members of the Association of Military Surgeons of the United States. Five copies of the competitive paper must be furnished, identified by a nom de plume. They must be forwarded to the secretary of the association of military surgeons not later than August 15 accompanied by a sealed envelop marked on the outside with the fictitious name or device assumed by the writer and enclosing his true name, title and address. The length of the essays is fixed between a maximum of 10,000 words and a minimum of 3,000 words. Further information may be had from the secretary of the association, Army Medical Museum, Washington, D. C.

### Change in Typhoid-Paratyphoid Vaccine

As the result of investigations into the quality and protective value of the army typhoid prophylactic over a period of many years, it has been decided to discard the paratyphoid A fraction and to increase the content of typhoid bacilli to 2,000 million per cubic centimeter, the dosage (0.5, 1 and 1 cc). The method of administration will remain as at present. The new vaccine will be placed in use at all army installations on August 1, when the old vaccine is either to be discarded or returned to the Army Medical School. In 1928 the paratyphoid B fraction was discarded as being no longer required.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

June 23, 1934

#### The National Health

In the house of commons, Sir E. Hilton Young, minister of health, introduced a vote of \$9,800,000 for the salaries and expenses of the ministry. He pointed out that between 1919 and 1934 the vote had increased as a whole by the enormous figure of \$290,000,000, rising from \$65,000,000 to \$355,000,000. Half of that increase, however, had been caused by the derating bill, which transferred cost from local to national taxation. Of this expenditure of \$355,000,000, \$200,000,000 was the block grant to local authorities, \$57,000,000 was the state expenditure on pensions and \$70,000,000 on housing. The whole expenditure depended entirely on the policy laid down by the house of commons and was not susceptible of increase or decrease by any administrative action, except over a small margin.

He next dealt with the standard of the national physique and health, as shown by the incidence of disease in the country and the resistance to it. On this matter it was possible to give a more positive opinion than with regard to malnutrition, because the results were reflected much more in actual figures. The most conclusive was the general death rate, which was sensitive to epidemics. It took a sharp rise in the influenza year of 1929. The general death rate showed a downward tendency, which was the best proof of the general maintenance of national health and physique. Today the death rate was 10 per cent lower than five years ago, in spite of the fact that the population, owing to the fall in the birth rate, was getting older in its average age.

#### THE INFANT DEATH RATE

During the last ten years the improvement in the infant death rate was such that every year 40,000 more infants under the age of 1 year are saved than were at the beginning of the century. This was due to education of mothers in the care of infants. He paid a tribute to the magnificent work done at the 1,300 antenatal clinics and 2,800 infant welfare centers, also to the thousands of health visitors and nurses who worked in the houses of the people. In the last fifteen years the death rate of children under 5 years of age had been brought down by one half in the three diseases most fatal to them—bronchitis, diarrhea and measles. Where one person in 1932 died from whooping cough, diphtheria, scarlet fever and typhoid, the figures at the beginning of the century were respectively four, four, seven and twenty-two. Brilliant successes had been made in this field, where the positive carrier could be studied—in water, milk, some insect or food. The difficulty was where infection was carried from person to person. Overcrowding was the principal cause of this and clamored for a national remedy. Compared with ten years ago the death rate from tuberculosis had declined 22 per cent.

#### STERILIZATION OF THE MENTALLY DEFICIENT

The reports as to lunacy and mental deficiency were less favorable. He had been impressed by the report of the committee recommending voluntary sterilization of the mentally unfit. But it was a novel question and one not yet thought out by the mind and heart of the nation. It would be wrong to press a national policy without making sure that it would give no offense to the national conscience.

#### THE MATERNITY DEATH RATE

Though there had been a decrease in the maternity death rate, the position was not as favorable as it should be. They must

press for a better development of maternity services. During the year, 147 more clinics had been opened.

#### SLUM CLEARANCE

There had been tremendous activity in the slum clearance campaign. During 1933-1934 some 2,250 slum areas had been declared, covering 37,000 houses and 172,000 people. There had been a boom in the building of small houses, which were being constructed at the rate of 300,000 a year, and of these 155,000 were for lower paid wage earners. But rents were still not low enough and were excessive in comparison with the cost of other necessities.

#### Tax on Carbon Arc Lamps Used in Hospitals

In the house of commons an amendment was moved to reduce the duty on carbon arc lamps of more than 14 mm in diameter from \$1.25 to 36 cents, because such lamps are used in therapeutics. A member stated that the consulting engineer of St. Bartholomew's Hospital told him that after long and laborious experiments he found that the imported article was the only carbon that could be relied on to give perfect treatment without risk to the patient and to the satisfaction of the physician. Replying for the government, Dr. Burgin, secretary of the board of trade, made a point of the fact that the hospitals had not made representations to him on the tax, but he was reminded that the reason for this was that they were reluctant to mix in a political matter and that the duty would raise the cost of light therapy. Dr. Burgin said that the duty was granted under conditions by which the consumer was protected, ignoring, as usual, with taxes of imports, the fact that the free entry of the foreign article was the best possible protection for the consumer, and therefore objectionable to the manufacturers here.

#### Memorial to Sir Walter Fletcher

A committee including Mr. Stanley Baldwin, the president of the Royal Society and the Royal Colleges of Physicians and Surgeons has appealed in the *Times* for subscriptions to establish a laboratory as a memorial to Sir Walter Morley Fletcher, the first secretary of the Medical Research Council, who died a year ago when in the height of his powers. A brilliant investigator and influential teacher at Cambridge, he became known over the world as a great organizer of research. It is proposed to place a portrait bust in the entrance hall of the National Institute for Medical Research and to build a Walter Fletcher Laboratory to be devoted particularly to those nutritional studies in which he was keenly interested.

#### Quarantine Farms for Tuberculous Cattle

A correspondent of the *Times*, Mr. B. H. G. Arkwright, brings forward a novel method of dealing with tuberculous cattle in dairy herds. He points out that the chief difficulties in any system of eradication lies in the insanitary buildings and segregation possibilities. These difficulties could be overcome by having quarantine farms for animals reacting to the tuberculin test. All animals yielding tuberculous milk should be destroyed and no milk cow that reacted to the contagious abortion test should be admitted to the quarantine farm. The advantages of the scheme are as follows: 1. The cows admitted need not be at once destroyed, because their milk would be fit for consumption after pasteurization for if 40 per cent of dairy stock, as estimated, would react to the tuberculin test and if, as also estimated, only 0.5 per cent of dairy stock yield tuberculous milk, the bulk milk from the quarantine farm would be a purer supply than that from a farm in which a milk from reactors, nonreactors and undetected yielders of tuberculous milk is bulked (for all the yielders of tuberculous milk have been eliminated). 2. The difficulties of segregation of reactors from nonreactors have been abolished. 3. The

reconditioning of buildings might (after drastic disinfection subsequent to removal of the reactors to the quarantine farm) be done in a more economical manner. 4 The calves of high yielding reacting cows born in the quarantine farm could be saved to their owners on condition of removal at birth from their dams to uninfected surroundings, since almost no calves are born tuberculous. 5 The present temptation to pass deep-milking reacting cows round the markets, so disseminating infection, would lose its economic urge, since the owner would not be deprived of the profit from a cow that he wishes to discard but cannot afford to sacrifice.

#### The Payment of Physicians for Road Accidents

In view of the enormous amount of service rendered by physicians in the treatment of road accidents for which no payment is received, members of the house of commons who are specially interested decided that the following new clauses be proposed for the road traffic bill now before parliament. 1 Where medical or surgical treatment or examination is immediately required for bodily injury (including fatal injury) caused by a road accident the owner of the vehicle shall pay to the physician (a) a fee of \$3 in respect of each person injured and (b) a sum in respect of any distance in excess of two miles of the journey from and back to the place from which the physician is summoned of 12 cents for every complete mile or part of a mile of that distance. 2 Where emergency treatment is carried out in a hospital the foregoing fee shall be paid to it.

#### The Training of Midwives

The sixth congress of the International Midwives' Union was held in London, when over 300 delegates from fifteen countries were present. The first subject of discussion was 'The Training and Education of Midwives'. Miss E. M. Pye, president of the congress and president of the Midwives' Institute, said in her presidential address that it was agreed that a midwife must be highly trained and skilled, but there were amazing differences of opinion as to what that training should be. The length of time considered necessary varied in different countries between six months and three and one-half years. The United States where maternal mortality was high had ignored almost entirely the midwife problem and was only now beginning to realize that it demanded urgent attention. The habit in England (where there were about 56,000 midwives on the roll but only about 14,000 practicing) for most trained nurses to take their midwifery diploma without any intention to practice midwifery led to great waste of teaching material. On the question of the limitation of the number of pupils accepted for training, the principal factors affecting it were the falling birth rate, the increasing number of women who went into institutions for childbirth, and in some countries the competition of the medical profession. In Great Britain there was a strong and increasing demand for sedatives and analgesics to deaden pain, and also a demand both from the midwives and from the public that midwives should be allowed to use all the alleviations that were safe in their hands and taught their use. In the subsequent discussion Mrs. Mitchell, deputy chairman of the Midwives' Institute, said that it was essential that something should be done to improve the financial position of midwives and that there should be some limitation to the number trained. Mme. Roger stated that in France the number of midwives did not exceed 10,500 but that there was a surplus. It was absolutely necessary to stem the ever increasing flow of candidates. French midwives were unanimously opposed to the principle of supervision or control, which they considered would undermine their prestige. Mme. Rembaut described a similar overcrowding of the profession in Belgium.

#### PARIS

(From Our Regular Correspondent)

May 30, 1934

#### New Diseases in the Paris Region

In Professor Nicolle's book, analyzed in a recent letter, it was predicted that, while certain infectious diseases will gradually disappear under the efforts of preventive hygiene and therapeutics, others will appear in areas in which they were unknown, owing to the greater facilities for their dissemination and the rapidity with which, because of the newer means of transportation, their causative agents are propagated. It is quite likely that some day yellow fever will be carried from Senegal to northern Africa and possibly to the European countries on the Mediterranean, as a result of the transportation of certain species of *Stegomyia* by commercial airplanes. In the environs of Paris, a case of mouse typhus and a case of autochthonous malaria have occurred in a restricted area in which these two diseases have been previously unknown. The case of mouse typhus was naturally wrongly diagnosed at first by the physicians who observed it, as they had never encountered a case before. The patient was a young woman in whom an intense fever was observed over a period of eight days, with generalized macular erythema, a meningeal syndrome and spinal leukocytosis. Serodiagnostics ruled out the paratyphoids. The correct diagnosis was not made until a month after recovery by a positive Weil-Felix reaction of 1:500, which became negative a month later. The patient lived near a farm infested with rats. Professor Brumpt discovered, a short time ago, in the brain of rats captured in Paris and the environs, the presence of typhus virus. This fact causes anxiety, for it awakens the fear that the disease, heretofore unknown in Paris, may make its appearance.

R. Marin Chassigneux and Rouesse, in a communication presented by Mr. Marchoux to the Academy of Sciences, have reported a case of autochthonous malaria in a woman living in the vicinity of the Asile de Maison Blanche, where there are hospitalized a number of patients with dementia paralytica to whom malaria therapy has been previously applied. The transmission of inoculation malaria being experimentally possible, the reported observation appears to reveal the danger associated with the placement in rural hostels of dementia paralytica patients who have been inoculated with malaria since the common culex is capable of transporting occasionally the hematooxon from an infected to a healthy subject if his bite is sufficiently deep and reaches the blood capillaries. A number of such cases were observed during the war in the vicinity of camps of colonial troops. But that never resulted in the creation of indigenous foci of autochthonous malaria.

#### Studies on a Pathogenic Principle of Neoplasms

In a communication presented to the Academy of Sciences by Besredka and Gross, these authors reported the results of research at the Institut Pasteur de Paris on the pathogenic principle contained in neoplasms produced by inoculation in the mouse. The tumor involved was the Ehrlich sarcoma, the virulence of which was considerably increased by serial reimplantation. This principle, not yet isolated, is found not only in the neoplastic tissues but also in the blood and the other organs of the infected mouse. It is not known whether a filtrable virus is involved, and it does not appear to be cultivable but it is affected by physical agents and may be destroyed by heat (between 40 and 43 C., depending on the duration of the exposure). The principle is extracted from fresh tumors finely ground and emulsified, the emulsion being afterward clarified by repeated centrifugations. The fluid inoculated in infinitesimal doses in mice causes the constant appearance of the same type of sarcoma. The inoculation may be negative

if the animal has already received a previous positive inoculation. An excision of the tumor, although complete, is usually followed by a rapid recurrence at the same site or a generalization by metastasis. Inoculation of the residues of centrifugation, composed of ground cells changed beyond recognition, is negative. The idea of a graft can therefore be discarded. Consequently, Besredka advances the hypothesis that the more or less malignant tumor is a defense reaction of the organism toward a virus that is widespread in nature, as is the staphylococcus, for example, but much more delicate than the staphylococcus. It can be easily destroyed by physical or mechanical agents and cannot develop spontaneously other than in tissues whose natural immunity has been diminished. The sensitiveness of this virus to heat may serve to explain the rarity of sarcomas in tropical countries and likewise spontaneous recoveries sometimes observed during the progress of erysipelas, while it justifies also trials of treatment with induced hypothermia and pyretotherapy.

### BERLIN

(From Our Regular Correspondent)

May 28, 1934

#### A Discussion of the Vitamins and the Weather

The meeting of the Gesellschaft für Verdauungs- und Stoffwechselkrankheiten, was held this year, jointly with the Gesellschaft für innere Medizin in Wiesbaden. Stepp of Breslau presented a paper on the vitamin theory giving a survey of the changes in the conceptions during recent years. Injuries due to lack of vitamins may, under certain conditions, he said, come to light only after many years or even in the next generation.

Rominger of Kiel spoke on the significance of vitamin D for metabolism and nutrition. He brought out that it was not yet proved whether the antirachitic active principle of cod liver oil is identical with viosterol. Through the irradiation of ergosterol, toxic by-products arise, which in nonrachitic animals lead to hypercalcemia, dystrophia and sclerosis of the arteries and of most internal organs. In the absence of proper indications, the administration of vitamin D to a nonrachitic organism is not without its dangers. That rickets is a disease due to the absence of vitamins is doubtful since cod liver oil heated to 120 C can cure rickets. Under the present conditions of nutrition in Germany only a small quantity of vitamin D is ingested, for which reason rickets is in central Europe the most frequent avitaminosis. Hypophosphatemia is a characteristic symptom. Before the appearance of a negative calcium balance a negative phosphorus balance is present. The rachitic disturbance of metabolism arises when a certain calcium-phosphoric acid compound needed for bone building, and for the formation of which vitamin D is required, is absent. The ideal prophylaxis would be the distribution to the population of milk with a constant vitamin D content.

Further communications dealt with the mechanism of vitamin action. Kulman of Breslau brought out that the vitamins are not markedly specific for certain diseases. The avitaminoses are due, in the last analysis, to a disturbance of the normal correlation of diet factors.

Szent Györgyi, Szeged told how he attained the isolation of vitamin C. The first source of the vitamin was Hungarian paprika. Later he established the identity of vitamin C with ascorbic acid. Its synthetic preparation has been accomplished. The daily dose for infants is 20 mg., a hypervitaminosis in infants need not be feared.

Abderhalden of Halle presented a paper on the physiology of nutrition. Attention was called to experiments on the protein minimum. With the ingestion of a small quantity of protein (25 Gm.) complete bodily and mental performance was main-

tained over a period of four years. In the event of intercurrent diseases, the quantity of protein must be temporarily increased. From 60 to 80 Gm of protein daily is, on the average, sufficient. An exclusive bread diet is not adequate. The old view of the passage of fatty acids through the intestine in the form of soaps must be discarded, since the reaction of the small intestine is not sufficiently alkaline to effect saponification. Abderhalden holds that the human organism is able to form purine derivatives from other substances besides purine bodies. It is highly probable that also uric acid can be decomposed in the human organism. In human nutrition the diet must not only be adequate and complete but must also offer variety. It is an error to assume that the farmer is always nourished in the best manner, for frequently his diet is lacking in variety.

Grafe of Würzburg presented material on the progress in the pathology of nutrition. The problem of obesity is still unsolved, but the condition is probably due to a disturbance of balance. The reasons for the varying forms of distribution of the fat intake are unknown. Water metabolism must be particularly considered in connection with the problem of obesity. In the condition of undue leanness, there are usually disorders of appetite.

Von Tyszka, statistician of Hamburg, spoke on "Economics in Relation to Nutrition." As against the prewar period, the degree to which Germany is self sufficient from the standpoint of food supply has greatly increased.

#### DISEASE IN RELATION TO WEATHER

The weather, as W. Hilgers of Magdeburg brought out, is not limited to meteorological happenings—to measurable, visible and tangible meteorological elements. The troposphere surrounding the whole earth is a covering of air, which in its rotations acts on man. This influence is exerted through the so-called bodies of air, whose contacts with one another are termed "fronts." By studying the meteorological elements, the barometric changes and the nature and velocity of the winds, the approach of these bodies of air can often be foretold. They appear to be highly charged with electricity, which influences the nature of the air that opposes their advance, the effects of which extend for hundreds of kilometers. De Rudder assumes that these electrical charges, by way of the vegetative nervous system, are capable of producing disorders, which may induce complications of infectious diseases and may influence the growth of the causative agents in the body and thus contribute to the dissemination of infectious diseases. There is no evidence of a causal influence exerted by the weather on infectious agents. The course of infectious diseases, however, is probably greatly influenced by changes of weather. Many infections have a tendency to be so-called seasonal disorders, as, for example, intestinal disorders and infantile paralysis in the fall, and catarrhal disorders, pneumonia and tuberculosis in the spring. These outbreaks at different seasons may not be ascribed to changes in the weather, without further investigation.

#### Tasks Assigned to Certain Universities

In accordance with an order of the new minister of public instruction the University of Breslau, in collaboration with the universities of Göttingen, Kiel and Königsberg, has been assigned certain special scientific and political tasks. On these universities devolves the task of presenting a perfect realization of the idea of a national-socialist institution of higher learning for German youth. It is emphasized that, in the new Germany, university study constitutes a high privilege, and that particularly at the University of Breslau the student will be faced with great problems of a political and scientific nature, which he must do his utmost to master, in order that he may serve properly the Germany of the future.

## VIENNA

(From Our Regular Correspondent)

May 18, 1934

## Cancer of the Bronchus

In connection with the regular postgraduate courses at the Faculty of Medicine in Vienna, Prof Dr Kohler recently held a seminar on the diagnosis of cases of bronchial cancer in which metastases have developed. The diagnosis of the site and type of primary tumor is important. Certain tumors, such as sarcomas, which show a marked clinical resemblance to the metastasizing bronchial cancer, are easily influenced by roentgen treatment, whereas cancer of the bronchus does not yield readily to such treatment. Tumors of other organs frequently lead to metastases in the lungs, for example cancer of the breast, prostate, thyroid and stomach, and hypernephromas. Mediastinal stasis may develop in bronchial cancer, and it is often associated with compression of the superior vena cava. One observes also edema of the face and the upper extremities, likewise a dilatation of the veins of the thorax and the back. Differentiation of a primary tumor of the mediastinum from malignant goiter is often difficult. An exact history will aid. If, for some weeks or months before the appearance of mediastinal stasis, cough, expectoration and dyspnea were present, that points to cancer of the bronchus. The roentgenologic picture and the examination of the sputum may support this diagnosis. Repeated mild attacks of hemoptysis point to a primary focus in the lung or bronchus, likewise elastic fibers, leucine and tyrosine in the sputum.

Multiple tumor areas in both lungs point away from a primary tumor in the respiratory organs. 'Miliary carcinosis' of the lung is always secondary. This condition has often been observed in connection with cancer of the stomach, in which the symptoms such as appear in miliary pulmonary tuberculosis (but without fever) appeared and the diazo reaction remained negative.

Sometimes a primary tumor of one lung leads to metastases in the other lung. The different appearance of the roentgenograms of the primary tumors, as compared with the secondary tumors, aids in the diagnosis.
